Greifswald, 2013

Dekan: Prof. Dr. rer. nat. Klaus Fesser

1. Gutachter: Prof. Dr. rer. nat. Uwe Völker

2. Gutachter: Prof. Dr. Oscar Kuipers

**Tag der Promotion: 24.04.2014**

## 1. TABLE OF CONTENTS

1.	Table of Contents .....	3
2.	Summary .....	7
3.	Introduction .....	11
3.1	Stress responses .....	12
3.2	Central carbon metabolism.....	13
3.2.1	Regulation of CCM .....	18
3.3	Osmoprotection .....	20
3.4	Genomics and Proteomics .....	25
3.5	Aim of the study .....	30
4.	Materials and methods.....	33
4.1	List of abbreviations.....	33
4.2	Strains used in the study .....	34
4.3	Biphasic batch fermentation (performed by Dr. Beate Knoke, Stuttgart) .....	34
4.4	Growth conditions for transcriptome analysis by tiling arrays.....	35
4.4.1	Growth at 37°C.....	35
4.4.2	Growth in the presence of 1.2 M NaCl.....	36
4.4.3	Growth at 16°C.....	37
4.4.4	Growth at 51°C.....	37
4.4.5	Growth in M9 .....	37
4.5	Experiments for optimizing trypsin digestion of protein samples from sporulating <i>B. subtilis</i> ..	39
4.5.1	Growth in DSM media .....	39
4.5.2	Calculation of percentage of heat resistant endospores (heat kill assay).....	39
4.6	Chemostat based cultivations (performed by Michael Kohlstedt, Braunschweig).....	39
4.7	Sample harvesting for transcriptome analysis .....	40
4.8	RNA preparation .....	40
4.9	Gene expression profiling .....	41
4.9.1	Relative gene expression analysis .....	41
4.9.2	Tiling array design.....	43
4.9.3	Statistical and functional data analysis in Genedata Analyst .....	44
4.10	Protein isolation and estimation .....	44
4.10.1	Sample harvesting and preparation of protein lysate by cell disruption.....	44
4.10.2	Determination of protein concentrations by Ninhydrin assay .....	45
4.10.3	Determination of protein concentrations by Bradford assay .....	45
4.11	Proteolysis and purification of proteome samples.....	46
4.11.1	Proteolysis by trypsin .....	46
4.11.2	Purification and in-gel digestion of the proteins .....	46

4.11.3	Desalting of peptides by ZipTip® .....	47
4.12	Mass spectrometry .....	47
4.12.1	MS parameters –LTQ Velos Orbitrap .....	47

## 2. SUMMARY

---

The soil bacterium *Bacillus subtilis* is capable of surviving most of the ensuing environmental stress conditions. The dynamic nature of the soil habitat is manifested with varying amounts of nutrients, frequent flooding and drying and variation of other growth parameters like temperature, acidity, aeration etc. In order to survive through the wide range of challenges posed by the environment, *B. subtilis* has evolved to employ very effective and complex adaptational responses. These adaptational responses are often multi-faceted and rely on well-orchestrated regulatory and metabolic networks involving changes in gene expression, control of protein synthesis and modification and adjustments of cellular metabolism. Hence comprehensive understanding of the adaptational responses requires generation and integration of data on multi-omics level. In the current study two major stress conditions were extensively investigated: 1) energy limitation/starvation which is achieved by limiting glucose in the growth medium, 2) osmostress resulting from frequent drying out of soil which is simulated by adding 1.2 M NaCl to the growth medium. In addition to osmostress, the naturally available osmoprotectant glycine betaine (GB) was supplemented to understand the simultaneous influence of osmostress and osmoprotection on cellular physiology.

Under conditions of hyperosmotic stress, *B. subtilis* produces high amounts of proline as an osmoprotectant via ProH, ProA and ProJ enzymes from glutamate that is replenished from the tricarboxylic acid cycle (TCA), whereas ProB, ProA and ProI satisfy the anabolic requirement of proline. In both pathways ProA is the common enzyme. As the central carbon metabolism (CCM) plays an important role for osmoadaptive synthesis of proline, the main aim of this study was the multi-omics based elucidation of the regulation of CCM during osmostress (NaCl) and osmoprotection (NaCl and GB) under glucose limiting conditions in chemostat cultures. To measure absolute protein abundances by mass spectrometry, a targeted approach (SRM –single reaction monitoring) using stable heavy isotope labeled artificial standard proteins known as QconCATs was optimized and implemented in the current study. The SRM technique in combination with QconCAT provided absolute quantitative data with high dynamic range for the 45 targeted CCM proteins across all the conditions measured. The resulting data were integrated with the other omics data sets obtained by transcriptome (microarray), metabolome and flux studies.

The analysis of global transcriptional changes during osmostress and osmoprotection revealed major changes including the down regulation of genes involved in utilization of specific carbon sources and chemotaxis during osmostress, which are partially or completely restored during osmoprotection. Other changes include the induction of the general stress response and the response to iron limitation during osmostress which was further increased during osmoprotection.

The multi-omics analysis of molecules involved in the CCM revealed differences between normal growth, osmostress and osmoprotection at mRNA, protein and metabolite levels. As expected, high amounts of proline were synthesized during osmostress. This was achieved by the significant increase in flux towards proline from the TCA and an increase of ProJ and ProH in both mRNA and protein amount, whereas ProA mRNA and protein remained almost unchanged. Though ProA was not regulated, the ProA protein was always present in higher amounts compared to the other proline metabolic enzymes and was thus sufficient to sustain proline synthesis during osmostress condition. However during osmoprotection all enzymes of proline biosynthesis were present in higher amounts, whereas the mRNA levels remained unchanged. This observation could be explained by the biophysical properties of GB that can promote protein stabilization by enhancing protein aggregation/complex formation. Similar observations could be made in a proteome analysis of a corresponding shake flask experiment under glucose excess conditions, in which 45 proteins previously described as unstable were stabilized in the presence of GB either during standard growth or at high osmolarity.

Detailed analysis of the CCM during simultaneous glucose limitation and osmostress revealed an upregulation of most of the genes and proteins involved in glycolysis. The part of the TCA cycle from oxaloacetate to 2-oxoglutarate, which supplies glutamate for proline biosynthesis was up-regulated, whereas the rest of the TCA cycle was either unchanged or down regulated. Though the protein concentrations of many enzymes increased, the flux through the core CCM was unaffected, a phenomenon that could be explained by the reduced catalytic activity of the enzymes at high intracellular ion ( $K^+$ ) concentration due to osmostress. Furthermore, the levels of many of the measured proteins further increased when GB was added to salt-stressed cells. This observation can be explained by the biophysical properties of GB and was most pronounced for the proteins known to interact within the CCM (e.g., CitZ, Icd, Mdh, PckA). On the other side during osmostress in the presence of excess glucose, proteins of the core CCM were not up-regulated in contrary to the observation during osmostress at low glucose. During osmostress at

high glucose the proteins of the CCM were already present at higher abundance to catalyze the degradation of excess glucose available; therefore the loss of catalytic activity of the CCM proteins due to osmostress was compensated with higher protein abundances. But the influence of osmostress on proline biosynthetic enzymes was similar whether the glucose concentration was low or high.

Osmostressed *B. subtilis* grew four times slower compared to normal growth conditions, even in the presence of excess glucose. Therefore, the limiting factors like the levels of ProH and ProJ and the glutamate availability were investigated. The overexpression of ProH and ProJ enzymes did not enhance growth of *B. subtilis*; furthermore the osmoadaptive production of proline did not increase to the same extent as the ProH and ProJ enzyme concentrations. This observation suggested that glutamate availability or the activity of these enzymes or ProA, the third enzyme involved in proline biosynthesis, might be the limiting factor. Supplementation of excess glutamate during osmostress could partially improve the growth rate, but the amount of the osmoprotective enzymes ProJ and ProH remained unchanged, whereas the anabolic route of proline biosynthesis (ProB and ProI) was up-regulated indicating a feed forward regulation.

As part of a joint study conducted by the BaCell-SysMO and BaSysBio consortia which aimed for the genome wide mapping of transcription units and previously unannotated RNAs of *B. subtilis* by means of tiling array hybridizations, we provided mRNA samples from growth at high and low temperatures (51°C and 16°C) and in the presence of 1.2 M NaCl, shake flask experiments during transition from exponential growth to the stationary phase, and high density batch fermentation. The results showed that glucose starvation influenced the highest number of genes compared to all other stress conditions, which was mainly due to strong upregulation of sporulation genes, which were not severely affected by the other stress conditions. Furthermore, there was very little overlap between the regulated genes in each of the tested conditions pointing to the diversity of the adaptational strategies employed by *B. subtilis*.

Time course analysis of exponentially growing *B. subtilis* and the transition to stationary phase was investigated in detail by high cell density fed-batch fermentation (glucose limitation) and batch fermentation (glucose exhaustion) with glucose as a limiting factor. Transcriptome analysis of the cells experiencing glucose limitation and glucose starvation revealed major differences and some similarities as well. Strong and transient upregulation of the SigB regulon mediating the general stress response was observed immediately after the onset of glucose

starvation whereas during glucose limitation the SigB regulon showed a rather weak and gradual increase. Sporulation response at transcriptome level was initiated within 150 to 180 minutes regardless of whether the cells entered glucose limitation or glucose starvation. A multi-omics analysis of the CCM for the batch fermentation was performed and the time course data was integrated and visualized. This analysis provided valuable insights into the dynamic changes between mRNA, proteins and metabolites.

In conclusion, pathway based multi-omics data were generated, integrated and visualized as a prerequisite for systems biology approaches and for a better understanding of the complex adaptational responses of *B. subtilis*.

---

### 3. INTRODUCTION

---

*Bacillus subtilis* is a non-pathogenic, rod shaped Gram-positive bacterium belonging to the most ubiquitous and diverse genus *Bacillus* that was discovered in 1872 (Cohn F.E, 1872). *B. subtilis* is an omnipresent bacterium found in a various habitats like water, soil, air, decomposing plant residue, intestinal tract of animals [11]. The type strains for *B. subtilis* are the Marburg strain NCTC3610 (National Collection of Type Cultures, London, GB) and ATCC6051 (American Type Culture Collection, Rockville, USA). Subsequent mutations to the strain ATCC6051 by ultraviolet and X-ray radiations led to the development of the strain commonly used laboratory strain 168 which is auxotrophic for tryptophan [12].

*B. subtilis* was the first nonpathogenic microorganism which was genetically transformed by Spizizen *et al.*[13] in 1961. Therefore, *B. subtilis* evolved to be a model organism for Gram-positive bacteria and holds an equivalent status as that of *Escherichia coli* which is a model organism for Gram-negative bacteria. The analysis of the complete genome of *B. subtilis* containing approximately 4200 genes started after the publication of the complete genome sequence by Kunst and coworkers in 1997 [14], which was recently updated by Barbe *et al.* 2009 [15] and Belda *et al* 2013 [16]. Analysis of several knock out mutants identified 271 genes to be essential for *B. subtilis* [17]. These studies also helped to raise interesting biological questions that subsequently led to understanding several genetic aspects of *B. subtilis*.

In addition to the scientific interests, the metabolic diversity of the members of the genus *Bacillus* led to profound usage in industrial processes like the production of carbohydrates, proteases and other enzymes. The most industrially prominent bacteria of the genus *Bacillus* are *B. licheniformis*, *B. pumilus*, *B. amyloliquefaciens* and *B. mojavensis* [18-20]. *B. subtilis* is one of the preferred workhorses among other bacteria because of its ability to acquire natural competence for the uptake of plasmid as well as the chromosomal DNA. This genetic property is exploited to understand and characterize the molecular phenotype and for the production of various extracellular enzymes like  $\alpha$ -amylase, dextranase, bio-surfactants and antibiotics etc. [21, 22] that have a high commercial importance. *B. subtilis* is also widely used in probiotic food products and in food processing industries leading to the approval of GRAS (generally regarded as safe) status by the US food and Drug Administration (FDA).

### 3.1 STRESS RESPONSES

*B. subtilis* has a complex lifecycle as it often encounters wide range of environmental stress conditions. In order to sustain in different conditions in its habitat, *B. subtilis* exhibits a very sophisticated network of adaptational responses. Depending on the availability of the nutrients *B. subtilis* can enter into one of the three main different genetic programs. These responses include entry into the stationary phase, which is comparable to the laboratory shake flask culture where a large number of stress dependent genes are regulated including morphological changes like motility. The second response is the development of competence which involves the binding, processing and internalizing of exogenous high molecular weight DNA[23]. When the two main alternative strategies fail, *B. subtilis* can enter the third and last ultimate response known as sporulation which is a highly organized process of the vegetative cell differentiating into dormant, dry and tough endospore resistant to most of the environmental stress conditions[24]. Apart from these, other kind of stress responses includes biofilm formation, antibiotic production and cannibalism etc.

All the above mentioned response strategies adopted by *B. subtilis* are a result of well-orchestrated global gene expression network controlled by various sigma factors associated to its core RNA polymerase. The sigma factor A ( $\sigma^A$ ) functions as general and housekeeping sigma factor and the rest of the sigma factors are considered as alternate sigma factors with specialized functions. The major alternate sigma factors in *B. subtilis* are SigB, SigD, SigH, SigL, SigW, SigE, SigF, SigG, and SigK[25]. The last four sigma factors (SigE, F, G and K) and SigH (early sporulation genes) are mainly involved in sporulation. SigL is involved in expression of degradative enzymes and metabolism of alternate carbon sources. SigD is involved in motility and chemotaxis. SigW along with few other sigma factors provide resistance to antimicrobial compounds [26]. SigB is the factor controlling the general stress response and receives signal cues from both energy and environmental stress responses[4].

Apart from these sigma factors there are several other DNA binding proteins that induce or repress the expression of their target genes in a given condition. The major pleiotropic transcriptional regulators in *B. subtilis* are CcpA, CcpN, TnrA and CodY. While CcpA and CcpN play an important role in carbon metabolism, TnrA regulates the nitrogen metabolism (discussed later in detail). CodY regulates branched chain amino acid synthesis, degradation of histamine and asparagine, competence, motility and sporulation [27]. The stringent factor RelA (ribosomal associated protein) indirectly regulates several genes involved in protein translation

and amino acid biosynthesis [28]. Accumulation of uncharged tRNAs at A site of ribosomes triggers the RelA dependent synthesis of (p)ppGpp that binds to RNA polymerase and inhibit the transcription of several genes that mainly code for components of the translational apparatus (rRNA, tRNA, elongation factors etc.) which is known as stringent response [28, 29].

---

### 3.2 CENTRAL CARBON METABOLISM

---

The central carbon metabolism (CCM) is an important fundamental component of metabolic network in all-living organisms. CCM consists of glycolysis, pentose phosphate pathway, tricarboxylic acid (TCA) cycle and other anaplerotic reactions that replenish the consumed metabolic intermediates. The major role of the CCM is to harnesses the chemical energy stored in carbohydrates for the production of precursors required for the biosynthesis of macromolecules (proteins, peptidoglycans, DNA, RNA, lipids etc.,) and for the production of energy currency of the cell i.e. ATP and NADH.

Glycolysis involves sequential conversion of glucose into pyruvate. Two German biologists Hans and Eduard Buchner brothers in 1897 using yeast lysate mentioned a first indication of glycolysis. Later in 1905, Harden and Young together reported ethanol production and proved that phosphate is required for the fermentation process using Yeast lysate. By 1940 all of the reactions of the glycolysis pathway were known from the research of Embden, Meyerhof, Parnas and Warburg, thus glycolysis is also known as the Embden-Meyerhof pathway as well. In 1937 Hans Krebs discovered a cyclic sequence of reactions that explained the oxidation of an unidentified 'triose' derived from glycolysis in pigeon breast muscle[30]. This pathway was later named as Krebs cycle or Citric acid cycle or Tri-Carboxylic Acid cycle (TCA cycle).

Glucose is the preferred source of carbon for most of the living organism including *B. subtilis*, as glucose can enter CCM directly without any further modifications. But availability of free glucose in natural habitat is often a rare scenario, so *B. subtilis* is able to secrete extracellular enzymes like amylase, gluconases etc., to degrade polysaccharides like amylose, glucans etc., into more simple monosaccharides like glucose. Glucose and other simple carbohydrates are then transported into the cells via an active and bifunctional transport system known as phosphoenol pyruvate-dependent sugar phosphotransferase (PTS) system [31, 32]. The PTS system is responsible for conversion and import of extracellular free glucose to glucose-6-phosphate (Glu-6-P). Intracellular glucose generated from degradation of di- or oligosaccharides

is converted to Glu-6-P by glucose kinase [33]. Glucose-6-phosphate isomerase (Pgi) performs a reversible isomerization of Glu-6-P to fructose-6-phosphate which is then phosphorylated to fructose-1,6-bis-phosphate (FBP) by 6-phosphofructokinase (PfkA) (Figure 1). One molecule of FBP is then split into two C-3 molecules, dihydroxyacetone phosphate (DHAP) and glyceraldehyde-3-phosphate (GAP) by fructose-bisphosphate aldolase. Isomerization/interconversion of DHAP to GAP is done by triose-phosphate isomerase (TpiA).

Figure 1 : Schematic representation of glycolysis, gluconeogenesis, TCA cycle and proline biosynthetic proteins in *B. subtilis*.

Subsequent enzymes required for the conversion of GAP to phosphoenol pyruvate (PEP) are encoded in a single operon (*cggR-gapA-pgk-tpi-pgm-eno*). The first gene product of *cggR* (central glycolytic genes regulator) [34] is the repressor of this operon. This repression effect by CggR is antagonized by FBP that increases during glycolytic growth conditions[35]. Apart from CggR all other members of this operon are glycolytic enzymes, which are present in high abundance. This differential abundance is achieved by RNase Y an endoribonuclease that cleaves between mRNA of *cggR* and *gapA* generating two mature transcripts with different stabilities (Figure 2). While the transcript of *cggR* is unstable, the transcript of *gapA* is stabilized

due to the presence of stem-loop at the 5' end [36]. The final step of glycolysis involves the conversion of PEP to pyruvate mediated by pyruvate kinase. The net energy yield of glycolysis is 2 molecules of ATP and NADH for each glucose molecule.

Figure 2: Stabilization mechanism of gapA mRNA. Processing of *cggR* and *gapA* transcript by RNase Y [10]. RNaseY cleaves the bicistronic transcript inbetween the two hairpin loop structures leaving behind the less stable *cggR* transcript and much stable transcript *gapA* which is protected on both ends by the hairpin structures (figure obtained from Martin *et al* 2012 [10])

When required *B. subtilis* can synthesize glucose from TCA cycle intermediates like oxaloacetate (OAA) and malate, this process is known as gluconeogenesis. Gluconeogenesis is important for *B. subtilis* when growing on TCA intermediates as the only carbon source [34, 37]. The main purpose of gluconeogenesis is to generate intermediates for anabolic growth such as glucose-6-phosphate to generate peptidoglycans (cell wall biosynthesis), also production of ribose-5-phosphate and glycerol-3-phosphate via pentose-phosphate shunt pathway [38]. All the enzymes that catalyze reversible reactions of glycolysis are part of gluconeogenesis, except for the irreversible enzymes like GapA, PfkA and PykA. Conversion of OAA to PEP is catalyzed by phosphoenolpyruvate carboxykinase (PckA) (Figure 1). When malate is supplied as the only carbon source to *B. subtilis* leads to induction of gluconeogenesis via four malic enzymes that generate pyruvate [39]. Among the four malic enzymes the malate dehydrogenase (Mdh) and the NADP-dependent malic enzyme (YtsJ) are essential for the growth of *B. subtilis* when malate is the only carbon source [40]. The other two enzymes are malic enzymes (MaeA and MleA), of which MaeA is known to be expressed only in the presence of malate [39]. Catalysis of glyceraldehyde-3-phosphate is performed by glyceraldehyde-3-phosphate dehydrogenase (GapB) which acts in exact opposite manner to GapA [34]. GapA is required when cell grow in glycolytic conditions, whereas GapB is required during gluconeogenic growth conditions. This differentiation is achieved for GapA and GapB by having different cofactor dependencies. While

GapA is only dependent on the co-factor NAD, whereas GapB is 50 fold more effective in presence of NADP compared to NAD [41]. De-phosphorylation of fructose-1,6-bisphosphate to fructose-6phosphate is catalyzed by fructose-1,6-bisphosphatase(fbp)[42].

Pyruvate from glycolysis has two fates: pyruvate is reduced to lactate catalyzed by lactate dehydrogenase (Ldh), with the simultaneous oxidation of one molecule of NADH[43] or the conversion of pyruvate to acetyl-CoA by pyruvate dehydrogenase complex(PdhA, PdhB, PdhC, PdhD) encoded by two operons *pdhAB* and *pdhCD*. This step generates one NADH molecule. Acetyl-CoA is then either converted to acetate by the enzyme acetate kinase (AckA), which is a part of overflow metabolism (discussed later) or enters into TCA cycle.

The first enzyme of TCA cycle is the citrate synthase (CitZ) that converts acetyl CoA and oxaloacetate from the cycle to citrate. This is an irreversible process; hence this is the rate limiting step of TCA cycle. Aconitase (CitB) catalyzes the conversion of citrate to isocitrate that is further reversibly converted to 2-oxoglutarate by isocitrate dehydrogenase (Icd). CitB is also known to be a RNA binding protein regulating iron metabolism [44].

The inter-conversion of 2-oxoglutarate to glutamate reversibly is marked as a key link between carbon and nitrogen metabolism, which is forward catalyzed by glutamate synthase (GltA and GltB known as GOGAT)[45]. Expression of GOGAT is facilitated by the binding of GltC, a transcription factor activated in the presence of glucose[46]. Repression of GOGAT is achieved in presence of the global nitrogen metabolism regulator TnrA which is activated in the absence of glutamine[47]. The reverse catalyzes of glutamate to 2-oxoglutarate is independently performed by two glutamate dehydrogenases- RocG and GudB (Figure 3A). However, *in vivo* only RocG is functionally active whereas GudB is enzymatically inactive[48]. Interestingly functional inactivation of RocG leads the *B. subtilis* to acquire spontaneous mutations that produce functional GudB[49] by an unknown mechanism. This regulatory mechanism signifies the role of glutamate in cellular metabolism. *In vivo* RocG expression is induced by the presence of nitrogen sources like arginine via two transcription factors AhrC and RocR along with the sigma factor SigL. CcpA represses RocG in presence of glucose. As glutamate is also generated by catabolism of several amino acids (including arginine, ornithine, histidine and proline), conversion of glutamate to 2-oxoglutarate creates the entry point for several amino acids into the TCA. Biosynthesis of proline is marked as the key protective mechanism when *B. subtilis* encounters hyperosmolar conditions (see below).

Figure 3: Regulation of nitrogen metabolisms in *B. subtilis*. A) The link between central carbon metabolism and nitrogen metabolism. B) Regulation of the gene glutamate dehydrogenase (*rocG*) in presence of arginine and glucose (Figure obtained from Katrin *et al* 2012 [3]).

Conversion of 2-oxoglutarate to succinyl-CoA is catalyzed by a complex of 3 subunits i.e., 2-oxoglutarate dehydrogenase (E1 subunit-OdhA and E2 subunit-OdhB) and PdhD(dihydrolipoamide dehydrogenase or E3 subunit of pyruvate dehydrogenase). Succinyl-CoA is dephosphorylated to succinate by SucC and SucD (succinyl-CoA synthase beta and alpha subunits) generating a GTP. Succinate is oxidized to fumarate by a complex of succinate dehydrogenase(SucA, SucB and SucC) generating a  $\text{FADH}_2$ . Fumarate is hydrated to malate by fumarase (CitG). Malate is oxidized to oxaloacetate by malate dehydrogenase (Mdh) generating a  $\text{NADH}_2$  thereby completing the cycle. To summarize the TCA cycle, one molecule of acetyl-coA is completely oxidized to two molecules of  $\text{CO}_2$ , yielding three molecules of NADH, one molecule of NADPH,  $\text{FADH}$  and GTP. Reducing equivalents like NADH and  $\text{FADH}$  are oxidized via oxidative phosphorylation for the production of ATP whereas NADPH is used in the anabolic reactions.

As the TCA cycle intermediates are also used for other metabolic processes, to maintain a steady state within the pathway there are several ways to replenish the metabolic intermediates. This process is known as anaplerosis. The main anaplerotic step that branches from glycolysis and replenishes OAA for sustained TCA cycle involves the conversion of pyruvate to OAA by pyruvate carboxylase (PycA) with the consumption of one ATP[50]. Oxaloacetate (OAA) is also generated from transamination of aspartate. Succinyl-CoA which is a product of  $\beta$ -oxidation of fatty acids is also an anaplerotic step for TCA cycle.

---

### 3.2.1 Regulation of CCM

---

Central carbon metabolism is a robust process which is stringently controlled depending on the extracellular nutrition and intracellular energy levels. Presence of glucose in the growth medium leads to the accumulation of fructose-1,6-bis-phosphate which is an activator of CcpA which in turn shuts down the expression of all the genes responsible for utilization of secondary carbon source, this phenomenon is termed as carbon catabolite repression(CCR)[35]. CcpA is a pleiotropic global regulator of carbon metabolism which interacts with phosphorylated forms of ATP dependent HPr(component of PTS system) and its paralogue Crh. This binding leads to strengthening the affinity of CcpA for *cre* sites (12-base pair sequence preceding promoter of target genes) and regulating the target genes. Both HPr and Crh are phosphorylated on serine by HPr kinase/phosphorylase in the presence of fructose-1,6-bis-phosphate (FBP) [32, 51]. Unlike Hpr, Crh cannot be phosphorylated on His-15 which acts as a phosphate donor during glucose import and hence Crh is not a part of phospho transfer system[52]. Glucose-6-phosphate and FBP are also known to interact directly to CcpA and affect its activity. Both the non-phosphorylated forms of Hpr and Crh (that are accumulated during gluconeogenic growth) can bind to GapA (glyceraldehyde-3-phosphate) and are able to inhibit GapA activity. In addition, the non-phosphorylated form of Crh has an inhibitory role for methylglyoxal synthase (MgsA) that catalyzes the conversion of dihydroxyacetone phosphate to methylglyoxal. This step creates a bypass from glycolysis to relieve the cells from sugar-phosphate stress under surplus glucose availability which may lead to a condition where a carbohydrate uptake rate exceeds the capacity of the lower branch of the glycolysis [53].

Genes that encode CitZ, Icd together with one more gene *mdh/citH* which encodes malate dehydrogenase (Mdh) are present in one operon[54] that is repressed by CcpA, however, the aconitase gene(*citB*) is encoded elsewhere on the chromosome[55]. Transcription from the *citZ* and *citB* promoters is repressed by CcpC, a member of the LysR family of regulatory proteins. CcpC is repressed by accumulation of citrate[56]. *citB* is also repressed by CodY and by AbrB in the early stationary phase [57]. Activity of CodY is in turn dependent on cellular GTP and branched chain amino acids. To summarize, three regulatory proteins CcpC, CcpA and CodY which depend in their corresponding four metabolites citrate, FBP, GTP or isoleucine or valine respectively function together to determine the extent to which pyruvate and acetyl CoA enter the TCA cycle [58].

A recent study by Meyer *et al.* 2011[59] revealed that the proteins CitZ, Icd and Mdh that are expressed from a single operon interact with each other and from the core of the TCA cycle metabolon. A metabolon is defined as a group of enzymes from a specific pathway that might form complexes. Formation of metabolon prevents the escape of substrates and intermediates by diffusion resulting in higher efficiency of the pathways[60]. Mdh also interacts with PEP carboxy kinase (PckA) and NADH dehydrogenase, this metabolon is prominent during gluconeogenesis. Isocitrate dehydrogenase (Icd) also interacts with glutamate synthase (GltA and GltB), this interaction leads to the channeling of 2-oxoglutarate from Icd to GltA and GltB[59]. Glycolytic enzymes like Pfk, Pgm and Eno are also known to form a metabolon[61].

Presence of Glucose in the growth medium also leads to overflow metabolism caused by the repression of TCA cycle. This leads to accumulation of pyruvate and acetyl CoA which are converted to lactate, acetate and acetoin and excreted into the extracellular environment[58]. Conversion of acetyl-CoA to acetate by phosphotransacetylase and acetate kinase generates an additional ATP. However, *B. subtilis* cannot survive with acetate as the sole carbon source due to the absence of glyoxylate pathway[62]. Conversion of pyruvate to lactate by the enzyme lactate dehydrogenase regenerates the co factor  $\text{NAD}^+$  required by the glycolytic enzymes for substrate oxidation; this process is also familiar in humans for causing muscle fatigue during rapid exercise. Later when the glucose is depleted both lactate and acetate are reimported and introduced to TCA cycle for the production of more NADH and ATP. Thus, the main advantage of the overflow metabolism is to replenish  $\text{NAD}^+$  and sustain continued glycolysis during two possible conditions; availability of excess glucose and nitrogen[63], unavailability of terminal electron acceptors like oxygen and nitrogen[43]. In *B. subtilis* overflow metabolism is regulated by the global regulators CcpA and CodY. Mutants of TCA cycle enzymes are able to grow vegetatively with reduced growth rate but sporulation efficiency is significantly decreased. The decrease in sporulation is due to the reduced energy supply, availability of intermediates and phosphorylation of Spo0A is effected which is a key regulatory protein for sporulation [64, 65].

Enzymes that exclusively participate in gluconeogenesis are repressed in the presence of glucose. Expression of PckA and GapB is strongly repressed in the presence of glucose by the regulator CcpN as the expression of these two gluconeogenic enzymes is futile to the glucose flux. As CcpN is constitutively expressed, it can sense the energy charge state of the cell by sensing the ATP/ADP levels thereby enhancing/decreasing the repression effect over its target genes[66]. CcpN competes with RNA polymerase there by inhibits expression of its target genes. A change in the conformation in the presence of ADP can relieve CcpN from RNA polymerase and

activating its target genes expression. Hence CcpN is very essential in maintaining carbon flux through CCM.

The other important enzyme of gluconeogenesis Fbp(fructose-1,6-bis phosphatase) is a constitutively expressed protein and is not subjected to catabolite repression[42]. Interestingly, an *fbp* mutant strain of *B. subtilis* is able to grow on gluconeogenic carbon sources such as glycerol and malate, however, no paralogue of Fbp enzyme has been found till date[42]. Adding to this, the *fbp* gene from *B. subtilis* has no orthologs in any other species [42].

### 3.3 OSMOPROTECTION

High salinity and fluctuating temperature are common conditions encountered by *B. subtilis* being a soil bacterium. Exposure of microorganisms to an environment of high salinity will result in excessive water efflux and destruction of the positive turgor (Figure 4) that is generally regarded as the driving force for cell growth and division[67]. Unlike eukaryotes, bacteria cannot actively transport water to maintain this turgor balance[68]. Thus, maintaining cytoplasmic hydration for the unhindered physiological activity is of great importance, this is accomplished by accumulating compatible solutes either by biosynthesis or by active uptake. Compatible solutes accomplish osmoprotection and do not interfere with cell physiology, even at a high concentration in the cytoplasm. Osmoprotectants, such as glycine betaine, proline, proline betaine, ectoine, carnitine besides maintaining cellular turgor pressure also function as kosmotropes, compounds that stabilize the conformations of biological macromolecules [69]. In addition to their role in osmoprotection, compatible solutes were identified to possess multifaceted functions, including thermoprotection, and stabilization of proteins and cell components against the denaturing effects of high ionic strength [70, 71].

The majority of the uptake of osmoprotectants or its precursors in *B. subtilis* is realized by specific transporters (osmoprotectant uptake systems) OpuA, OpuB, OpuC, OpuD and OpuE. These transporters are either multi-component import systems in case of OpuA (OpuAA, OpuAB, OpuAC), OpuB (OpuBA, OpuBB, OpuBC, OpuBD) and OpuC (OpuCA, OpuCB, OpuCC, OpuCD) or single-component transporters for OpuD and OpuE (Figure 5A). OpuD is responsible for only glycine betaine import and OpuE is responsible for proline import alone. OpuE is highly similar to that of proline inducible PutP permeases in *E. coli* which is used to import proline as carbon and nitrogen source but not for osmoprotection, which signifies the

evolutionary conservation for the same function[68]. Deletion of OpuE leads to inability of *B. subtilis* to use exogenously provided proline during high osmolar conditions[72]. The ability to import wide range of osmoprotectants by *B. subtilis* imparts the unique flexible adaptation to various high osmolality ecological niches.

Figure 4: When the bacterial cells encounter high osmolar environment, to maintain the turgor pressure on either side of the cell membrane, cells loose water due to exo osmosis resulting in plasmolysis. To avoid plasmolysis cells accumulate osmoprotectants such as proline and glycine betaine

*In vivo*, the primary osmotic stress response in *B. subtilis* is to rapidly accumulate  $K^+$  ions from the environment via two different  $K^+$  uptake systems (KtrAB and KtrCD)[73]. However uptake of  $K^+$  is a short-term response because high intracellular ionic strength is deleterious to cellular physiology [74, 75]. Subsequently, accumulation of  $K^+$  ions is followed by long-term accumulation of compatible osmoprotectants like proline[76]. Proline/other osmoprotectants like glycine betaine are either imported or synthesized intracellular from glutamate in order to decrease the  $K^+$  intracellular concentration. Synthesis of proline takes place in two different ways: for anabolic synthesis and for osmoprotection [77](Figure 5B). Anabolic synthesis involves synthesis of proline from glutamate that involve three enzymes:  $\gamma$ -glutamyl kinase (ProB), the  $\gamma$ -glutamyl-phosphate reductase (ProA) and the  $\Delta$ -pyrroline-5-carboxylase reductase (ProI) (Figure 5B) [78]. The activity of the ProB enzyme from *B. subtilis* is subjected to feedback control by proline [77]. The anabolic biosynthetic pathway involving *proB-proA* operon and that of the *proI* gene is regulated through a proline-responsive T-box regulatory system (RNA-based regulatory switches that regulate the levels of amino acids via

charged/uncharged tRNA) [77]. This pathway ensures that enough amount of intra cellular proline levels are maintained as building block for protein synthesis.

In addition to the anabolic pathway involving ProB–ProA–ProI enzymes, the second route for proline biosynthesis accounts for production of the large amounts of proline as an osmoprotectant[79]. This osmoadaptive proline biosynthetic route is formed by the ProJ– ProA– ProH enzymes, and relies on isoenzymes for the first and last steps. Therefore, the expression of the *proHJ* operon is strongly up-regulated in response to either sustained osmotic stress or sudden osmotic upshift, whereas that of the *proBA* operon (Figure 5C) or that of the *proA* gene alone is not osmotically induced [80, 81]. In addition to the ProI and ProH enzymes, the ProG protein also possesses D1-pyrroline-5-carboxylase reductase activity although the precise physiological regulation of the ProG protein has not been resolved yet. Data from two independent studies have shown that ProA was both cytosolic and membrane bound protein [2, 81], however the rest of the enzymes involved in the proline biosynthesis were not found in the membrane bound fraction. Steil *et al.* (2003) [80] for the first time reported the genome wide transcriptional analysis of a *sigB* mutant of *B. subtilis* during sudden osmotic upshift and adaptation to prolonged growth at high osmolarity. The authors have indicated that adaptation to sudden osmotic upshift and continuous growth at high osmolarity require different physiological adaptations by the *B. subtilis* cells as both the adaptations shared limited number of commonly regulated genes. Hahne *et al.* (2010) [81] have performed a comprehensive time course proteomic and transcriptomic analysis of *B. subtilis* during osmotic upshift. The authors reported the expression profiles for 590 proteins and 3961 mRNAs. The authors indicated that about 500 genes were up-regulated in response to osmotic upshift suggesting a dynamic physiological adaptation of *B. subtilis* towards osmotic stress.

Proline can act as a nutrient, where proline is catabolized to glutamate that is at the center of carbon and nitrogen metabolism (see above). In *B. subtilis* and other microorganisms the oxidation of proline to glutamate is catalyzed by PutB PRODH and the monofunctional PutC  $\Delta^1$ pyrroline-5-carboxylate dehydrogenase (PD5CD) [82, 83] that are products of the gene cluster *putBCP*. The last gene in the gene cluster *putP* encodes for the L-proline transporter PutP [84]. PutP has high affinity for extracellular proline intake compared to OpuE. Unlike other microorganisms the regulation of *putBCP* gene cluster in *B. subtilis* is under control of the proline-responsive PutR protein encoded by the gene *putR* [83]. It was shown recently by Moses *et al.* (2012) [83] that L-proline generated as a result of osmoprotection by the ProJ-ProA-ProH pathway does not induce *putBCP*, indicating that *B. subtilis* can somehow sense the difference between *de novo* synthesized L-proline and imported extracellular L-proline.

Glycine betaine is one of the important osmoprotectants next to proline that can be imported or synthesized *de novo* in the presence of choline. Glycine betaine is a prominent osmoprotectant that is available readily in the habitat of *B. subtilis* the soil, as it is one of the products released due to degradation of the plant tissues and roots [85]. The transporters OpuA, OpuC and OpuD import glycine betaine into the cell. Mutants of these transporters were not able to import glycine betaine suggesting that these are the only transporters that can import glycine betaine in *B. subtilis* [86]. OpuA and OpuC are multicomponent transporters that belong to ABC (ATP binding cassette) type super family, whereas OpuD is a single-component transporter. All these three transporters have low  $K_m$  signifying high affinity towards glycine betaine giving *B. subtilis* the ability to import glycine betaine even at very low extracellular concentrations. Even though these three transporters are expressed during osmotic upshift, OpuA contributes to the majority of the imported glycine betaine due to its high  $V_{max}$  over OpuC and OpuD [86].

Figure 5: Osmoprotectants import mechanisms and proline biosynthetic proteins. A) Different types of transporters of osmoprotectants into the cell during osmotic stress (figure modified from Bremer *et al.* 2002 [8]). B) Enzymes involved in proline biosynthesis as a result of osmotic stress and protein biosynthesis (figure obtained from Brill *et al.* 2011 [9]). C) Genetic arrangement of proline biosynthetic enzymes.

De novo synthesis of glycine betaine takes place in the presence of extracellular choline which is imported by the transporters OpuB and OpuC (Figure 5A). Imported choline is oxidized to glycine betaine in two steps that involves GbsB (choline dehydrogenase) and GbsA (glycine betaine synthesis) with glycine betaine-aldehyde as an intermediate [85]. The transcription of the operon *gbsA-gbsB* is enhanced under the presence of choline [87]. It has been shown that glycine betaine apart from being an osmoprotectant, can also offer thermo-protection at 52°C [70] and cold-protection at 13°C [88].

During osmotic down shock conditions like a rain fall or a washout, presence of intracellular osmoprotectants at high concentrations leads to influx of water into the cell there by increasing the turgor pressure inside the cells which can lead to cell lysis. *B. subtilis* overcomes this problem by employing two mechanosensitive channels MscL (large conductance) and MscS (small conductance). These channels are located on the cell membrane and they respond to changes in the tension of lipid bilayer which leads to the formation of transient aqueous pore through which solutes and solvents are released into the environment [75, 89]. This phenomenon allows *B. subtilis* to reduce the intracellular turgor and avoid cell lysis. Hoffmann *et al.* [89] have shown that the protein MscL prevents the lysis of *B. subtilis* that are osmotically down shocked during the early and mid-log phase growth period, whereas MscS is responsible for prevention of cell lysis during late log phase growth.

---

### 3.4 GENOMICS AND PROTEOMICS

---

Discovery of DNA structure in 1953 by Watson and Crick and invention of DNA sequencing technique by Fredrick Sanger in 1975 laid the foundation for the development of Genomics. The term ‘omics’ is often used when a large scale and holistic approach in understanding biological mechanism of life is addressed. Transcriptomics and proteomics are two of the several omics technologies available today.

The transcriptome is the set of total messenger RNA and their quantity in a tissue type or cell type for a developmental or physiological condition and transcriptomics is the term used for studying the transcriptome. There are different methods to study transcriptomics like DNA microarrays and more advanced recent RNA-seq (next generation sequencing); considering the past two decades the most popular and established method is the DNA microarray. A DNA microarray is defined as an orderly arrangement of thousands of identified sequenced genes (probes) printed on an impermeable solid support, usually glass, silicon chips or nylon membrane. There are different types of probes used in microarray, such as fragment of genomic DNA, cDNAs, PCR products or chemically synthesized oligonucleotides (up to 70mers). A single DNA microarray slide/chip may contain thousands of probes each representing a known single gene and collectively the entire genome of an organism. Oligonucleotide DNA microarray has an advantage over cDNA and PCR based microarray due to automation, speed of manufacturing and reproducibility. DNA microarrays works on the principle of hybridization, where a fluorescently labeled cDNA is hybridized onto a custom-made microarray or commercial high-density oligo microarray [90, 91].

The latest in the series of microarray technologies is the genome-wide tiling arrays which is a high-density oligo microarray. Unlike other DNA microarrays, tiling arrays contain probes that map the whole genome or region of interest including complete sense and anti-sense strands giving this technique many advantages like mapping non-protein-coding RNAs (ncRNAs), transcription unit mapping (genome annotation), mapping of DNA methylation sites (methylome) and comparative genome hybridization [92]. Recent tiling array analysis in

*B. subtilis* by Rasmussen *et al.* (2009) [93] showed 3662 transcriptional active regions (TARs) and newly identified 84 non-coding RNAs and 127 antisense transcripts; this signifies the importance of tiling array in modern day transcriptomics.

While genomics represents the genotype of an organism, the other omes (transcriptome, proteome and metabolome) measure how the genome is utilized under a particular situation, which is shaped by both the genotype and the environmental conditions of the organism. The proteome is the sum of proteins expressed in an organism, tissue type or cell under any specific condition and proteomics is the term for studying the proteome. Two major methods are being used for proteomic studies: the well-established two-dimensional gel electrophoresis (2DE) developed in 1975 (Klose, O'Farrell 1975) and more modern liquid-chromatography assisted mass spectrometry methods (LC-MS/MS).

Mass spectrometry has its roots in 1912 when JJ Thomson a British physicist analyzed isotopes of Neon by the instrument “parabola spectrograph” which later became much prominent during world war II for enrichment of Uranium isotopes [94]. With the invention of MALDI (matrix-assisted laser desorption/ionization) [95] and ESI (electro spray ionization)[96] in the 1980s mass spectrometry became indispensable for the development of proteomics and other “Omics” platforms. In the context of proteomics, both MALDI and ESI convert peptides and proteins into gaseous phase as the mass spectrometers work with vacuum. The ESI (electro spray ionization) is more prominent among shotgun proteomics work flow (a complex mixture of peptides sprayed simultaneously into a mass spectrometer). In a classical ‘bottom up’ shot gun proteomics approach; a complex mixture of proteins from a sample is digested to peptides by a sequence specific enzyme such as trypsin. The resulting peptide mixture is separated with a binary gradient of aqueous/organic solvent in a high-performance liquid chromatography (HPLC) equipped with a C18 based reverse phase columns, the gradient lasting about one to several hours to reduce the complexity of peptides entering the mass spectrometer at any given time. On the other side top down proteomics describes the analysis of intact proteins with mass spectrometry [97], which is currently a flourishing field.

The data obtained from the mass spectrometry based proteomics can be broadly used and classified into three categories; posttranslational modifications (PTMs), protein interactions (network biology/interactome) and much extensively used expression proteomics [98]. Expression proteomics deals with the relative or absolute amounts of the proteins in a sample

and can be compared to transcriptome data, but also unique information about subcellular protein localization can be obtained using expression proteomics.

Quantification in proteomics is of central importance and is of two kinds; relative and absolute quantification. Though relative quantification delivers enough data to differentiate and compare two or several different conditions, it cannot deliver absolute value/copy number of proteins per cell- an important input for systems biology. Absolute quantification in MS can be performed by spiking in stable isotope labeled peptide/protein standards (stable isotope dilution mass spectrometry: SID-MS) into the sample and by label free approach (spectral counting[99] and intensity based). Label free approaches are more error prone compared to the label-based approach due to sensitivity and reproducibility issues[98]. Stable isotope based absolute quantification involves spiking of standards like AQUA (absolute quantification) peptides [100], absolute SILAC proteins [101] and QconCAT (Quantification concatemers)[102]. Spiking-in of heavy isotope labeled reference peptides eliminates the ion suppression effect in MS measurements due to the identical retention times and fragmentation patterns of the reference peptide and the analyte peptide [103]. Quantification of multiple proteins of interest requires several heavy labeled AQUA peptides and proteins, this also introduces multiple pipetting steps during sample processing and sometimes this may result in inappropriate estimation of protein concentration. Furthermore, AQUA peptides are added at the end of the sample processing which implies that unlike the native peptides the AQUA peptides do not undergo the same treatment procedure leading to a biased estimation of protein concentrations. This problem can be avoided by using AQUA proteins, but the AQUA proteins are very expensive and laborious to produce compared to the AQUA peptides. On the other hand, the QconCAT based absolute quantification is a more cost effective and more accurate method due to involvement of less pipetting steps while performing multiplexed quantification for several proteins.

The QconCAT strategy relies on a heavy labeled artificial protein that is an assembly of signature Qpeptides derived from multiple proteins of interest. Qpeptides are designed to end with arginine or lysine at the C terminus as they represent and will be internal standards for tryptic peptides derived from digestion of the analyte proteins [102, 104]. Known concentrations of QconCATs are spiked to a complex mixture of analyte proteins and digested with trypsin to release both the stable isotope-labeled peptide and the native peptide from the analytes. From the known concentration of spiked QconCAT in to the analyte, absolute quantification of the target analyte proteins can be achieved.

Among the available MS techniques MRM (multiple reaction monitoring) is the best approach for targeted proteomics. MRM is performed by analyzing a predefined set of unique peptides of the corresponding proteins with optimized parameters. MRM performed in combination with stable isotope dilution on a triple quadrupole mass spectrometer is a very robust method for absolute quantitative measurement of target proteins [105]. Targeted mass spectrometry always has an advantage in terms of sensitivity over discovery proteomics. A comprehensive study by Picotti *et al.* (2009) [106] in yeast proved the sensitivity and dynamic range of MRM based absolute quantification for ~100 proteins ranging from 50 to 200000 copies/cell in a single MS analysis without the need for extensive prefractionation. Costenoble *et al.* (2011) had pushed the upper limit of MRM by performing absolute quantification of 228 proteins accounting for 95% of the central carbon metabolism including isoenzymes in budding yeast [107].

After whole genome sequencing of *B. subtilis* was performed in 1997 [14], several proteome and transcriptome studies were performed in the past but only a few targeted transcriptome and proteome studies were performed simultaneously to understand the intricate physiological mechanisms adopted by *B. subtilis* to survive in various stress conditions. For the first time a comprehensive characterization of proteome and transcriptome of *B. subtilis* was first done by Eymann *et al.* 2004[108] reporting a total 876 proteins and 2515 genes expressed in exponentially growing cells. Hahne *et al.* [109] performed a comprehensive studies comparing membrane proteome profiling of exponentially growing *B. subtilis*. The authors reported 527 integral membrane proteins covering up to 66% of the predicted membrane bound proteins. A recent comprehensive proteomic and transcriptome profiling of *B. subtilis* by Otto *et al.* 2010[2] reported 2142 proteins by extensive pre-fractionation of intracellular and membrane bound proteins in glucose starved *B. subtilis*.

In *B. subtilis* a large scale phosphoproteome study was performed by Macek *et al.* [110] identifying 103 protein phosphorylation sites; 54 on serine, 16 on threonine and 8 on tyrosine. Complementing the above study Elsholz *et al.* (2012) [111] demonstrated protein phosphorylation on arginine residues for 86 proteins. This study suggests the importance of the protein arginine kinase and phosphatase, MscB and YwiE respectively as regulators.

Development of techniques to analyze global scale gene and protein expression patterns provided great insight into complex cellular network organization. From the perspective of systems biology it is of great importance to have absolute quantitative data for any of the considered data sets (transcriptome, proteome, metabolome). Technological improvements to generate large scale quantitative data sets and multidisciplinary approaches during the last

decade has driven the increased interest in systems biology, a discipline encompassing data based mathematical modeling and simulation that help to understand the dynamic interactions of cells and components within cells[112]. Interest in the understanding of robust signaling networks that help *B. subtilis* to survive under changing environmental conditions has motivated numerous studies that involve mathematical modeling. A studies by Kleijn *et al.* (2010) [113] has shown through mathematical modeling of central carbon metabolism that malate is the second preferred carbon source which is co-utilized with glucose as well as the preferred gluconeogenic carbon source. The co-utilization of glucose and malate is a rare phenomenon among microorganisms as both carbon sources exert carbon catabolite repression against other carbon sources but not against each other. However, it is unclear how malate represses the uptake of other carbon sources. In a follow up multidisciplinary study, Buescher *et al.* (2012) [114] reported that adaptability of *B. subtilis* towards utilization of malate was faster primarily due to post-transcriptional regulation. On the other hand adaption towards glucose is slower primarily due to transcriptional regulation involving approximately regulation of half of the genes. The authors used comprehensive omics-based platforms such as transcriptome, proteome, metabolome, fluxome, promoter activity assays and finally integrated all the above-mentioned data to fit into a mathematical model.

Ferguson *et al.* (2012) had demonstrated the absolute quantification of promoter activity for the genes *cggR*, *gapB*, *pckA* and *ccpN*, as these genes primarily control the carbon flux in CCM [115]. The authors showed that the negative feedback regulation for strong promoters like *cggR* is not achieved by reduced transcriptional noise, rather it depends on burst size (number of mRNA molecules produced in one burst) which is proportional to the active state of the operator at the promoter. Contrarily, *ccpN* in order to maintain its repressive mechanism over *gapB* and *pckA* under glycolytic conditions has evolved to limit bursting and not allowing the RNA polymerase to escape from promoter leading to strong catabolite repression.

To summarize, advent of more sophisticated techniques in analyzing the transcriptome, proteome and metabolome in combination with mathematical modeling in recent years have enabled a deeper understanding of biological systems. Hence, in this study a combination of transcriptome, proteome and metabolome analysis will be applied to gain deeper understanding of the physiological adaptational mechanisms of *B. subtilis*. To my knowledge this is the first pathway targeted multi-omics study targeting the central carbon metabolism in *B. subtilis*.

---

### 3.5 AIM OF THE STUDY

---

*B. subtilis* is one of the best studied model organisms among Gram positive bacteria. Being a soil bacterium, the adaptational responses employed by *B. subtilis* are very complex often involving multiple regulatory networks that involve regulation of gene expression, protein expression and metabolite levels. Hence, comprehensive understanding of the complex adaptational responses deployed by *B. subtilis* requires generation and integration of data on multi-omics level. In the past only few studies have tried to understand the adaptational responses of *B. subtilis* at multi-omics level. Therefore, in the current study a multi-omics approach will be employed for a systems biology study.

Energy limitation or starvation for carbon is one of the key challenges faced by *B. subtilis* in its natural environment the soil. Hence, the time-resolved transition of *B. subtilis* from exponential phase to stationary phase will be investigated in high cell density fermentation where glucose will be the growth limiting factor.

When challenged with osmostress *B. subtilis* produces high amount of proline as an osmoprotectant from glutamate. Glutamate is mainly replenished from 2-oxoglutarate from the TCA cycle. Hence, central carbon metabolism and glucose play a crucial role during the osmostress. Therefore, a workflow for measuring mRNA, proteins and various metabolites involved in the central carbon metabolism and proline biosynthesis will be established and the data will be integrated for the better understanding of the adaptational responses. As a proof of concept, two major stress conditions will be simultaneously investigated in a controlled chemostat based cultivations. The conditions that are going to be investigated are 1) energy limitation which will be achieved by limiting glucose in the growth medium, 2) osmostress resulting from frequent drying out of soil will be achieved by adding 1.2 M NaCl to the growth medium. In addition to osmostress, the effect of naturally available osmoprotectant glycine betaine (GB) under simultaneous influence of osmostress and osmoprotection on cellular physiology will be investigated. Influence of high glucose concentration during osmostress and osmoprotection will also be investigated.

Information about the absolute protein abundances within a pathway will contribute to a better understanding of the adaptational mechanisms of *B. subtilis*. Hence, a method to quantify

absolute concentrations for the proteins involved in the central carbon metabolism and proline biosynthesis will be developed and implemented.

Complementing these experiments, global transcriptome analysis of other major stress conditions like growth at high temperature, low temperature, high salinity and late stationary phase will be performed to understand the transcriptional plasticity under different stress conditions in general.

## 4. MATERIALS AND METHODS

### 4.1 LIST OF ABBREVIATIONS

ACN	Acetonitrile
ANOVA	Analysis of variance
ATP	Adenosine triphosphate
BSA	Bovine serum albumin
CCM	Central Carbon Metabolism
CCR	Carbon Catabolite Repression
cDNA	copy DNA
Cy3/Cy5	Fluorescent dyes of the cyanine dye family
Dnase I	Deoxyribonuclease I
DTT	Dithiothreitol
EDTA	Ethylenediaminetetraacetic acid
FBP	Fructose-1,6-bisphosphate
FWHM	Full Width at Half Maximum (Resolution)
GB	Glycine Betaine
GTP	Guanosine TriPhosphate
IAA	Indoleacetic acid
LC-MS	Liquid Chromatography–Mass Spectrometry
PAGE	Polyacrylamide gel electrophoresis
PCA	Principal component analysis
QconCAT	Quantification concatamer
QQQ	Triple quadrupole mass spectrometer
SDS	Sodium dodecyl sulfate
Sig	RNA polymerase sigma factor
SRM/MRM	Selected Reaction Monitoring / Multiple Reaction Monitoring
TCA cycle	Tricarboxylic acid cycle
TE	Tris-EDTA
TPP	Trans-Proteomic Pipeline
UTP	Uridyl triphosphate

## 4.2 STRAINS USED IN THE STUDY

**Table 1 : *B. subtilis* strains used in the current study.**

Strain	Genotype	Construction	Phenotype	Reference
BSB1		Trp <sup>+</sup> derivative of <i>B. subtilis</i> 168	Trp <sup>+</sup>	[114, 116]
MO1027	<i>trpC2 pheA1 spoIVCB::erm</i>		Trp <sup>-</sup> Spo <sup>-</sup>	P. Stragier
BSG 112	<i>spoIVCB::erm</i>	Transformation of BSB1 with chromosomal DNA of MO1027	Trp <sup>+</sup> Spo <sup>-</sup>	Current study
JH642	<i>trpC2 pheA1</i>		Trp <sup>-</sup>	Laboratory stock (E. Bremer, Marburg)
MDB22	<i>trpC2 pheA1 ΔproHJ amyE::P(proHwt)-proH-proJ</i>	Details in results section 5.4.5	Trp <sup>-</sup>	Current study (Marburg)
MDB28	<i>trpC2 pheA1 ΔproHJ amyE::P(proH-M10)-proH-proJ</i>	Details in results section 5.4.5	Trp <sup>-</sup>	Current study (Marburg)

## 4.3 BIPHASIC BATCH FERMENTATION (PERFORMED BY DR. BEATE KNOKE, STUTTGART)

Precultures with 100 mL of LB medium (erythromycin – 1 µg/mL) was inoculated with the *Bacillus subtilis* strain-BSG112 and incubated for 4h at 37°C at 130 rpm orbital shaking. The batch fermentation was carried out in a 30 L bioreactor (Bioengineering AG) using minimal medium according to Hardiman *et al.* 2007 [117] but without thiamin-HCl, a reduced calcium concentration (7% [w/v]) and addition of 0.6 mg l<sup>-1</sup> sodium molybdate (Na<sub>2</sub>MoO<sub>4</sub> \* 2H<sub>2</sub>O). The following process parameters were applied: dissolved oxygen concentration > 50% saturation, pH 7, pressure of 0.5 bar, temperature of 37°C. The gas inflow (VG=10 l min<sup>-1</sup>) was monitored by a mass flow meter (Bioengineering AG) and foam formation was suppressed by the addition of polypropylene glycol P 2000 (Sigma–Aldrich) when necessary. Samples were taken at mid-log phase (OD<sub>600nm</sub> 1.7; t<sub>0</sub>) and 1.5 h and 5 h after glucose exhaustion (t<sub>1</sub> and t<sub>2</sub>, respectively).

### BM5 (batch medium): (10x per liter)

BM5 (10x)	Quantity
Na <sub>2</sub> SO <sub>4</sub> * 10 H <sub>2</sub> O	20 g
(NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub>	26.8 g

<b>NH<sub>4</sub>Cl</b>	10 g
<b>NaH<sub>2</sub>PO<sub>4</sub>·2H<sub>2</sub>O</b>	40.2 g
<b>K<sub>2</sub>HPO<sub>4</sub></b>	146 g

Autoclave and store at RT.

#### Trace elements (100x per liter):

Trace elements(10x)	Quantity
<b>CaCl<sub>2</sub>·2H<sub>2</sub>O</b>	1.0 g
<b>FeCl<sub>3</sub>·6H<sub>2</sub>O</b>	16.7 g
<b>Na<sub>2</sub> – EDTA</b>	20.1 g
<b>ZnSO<sub>4</sub>·7H<sub>2</sub>O</b>	0.18 g

## 4.4 GROWTH CONDITIONS FOR TRANSCRIPTOME ANALYSIS BY TILING ARRAYS

### 4.4.1 Growth at 37°C

Cultivations were performed as mentioned by Steil *et al.* (2003) [80]. Briefly, *B. subtilis* was grown for 24 h on a LB plate at 37°C and used to inoculate 100 mL of overnight Spizizen's minimal medium (SMM) media in a 500 mL-Erlenmeyer bacterial culture flask. Flasks were aerated by shaking at 220 RPM at 37°C in an orbital shaker (Innova 4230, New Brunswick, USA). A fresh 100 mL SMM (pre-culture) was inoculated to an optical density (OD) of 0.1 at 578 nm from the overnight cultures. After these pre-culture reached an OD<sub>578</sub> of 0.5, a fresh pre-warmed (37°C) 100 mL of main culture was inoculated with the pre-culture to a final OD<sub>578</sub> of 0.1 and the growth curve was followed. Samples for RNA isolation were harvested (as described in section 4.7) at OD<sub>578</sub> 1.0.

SMM (5x)	Quantity

#### **4.4.2 Growth in the presence of 1.2 M NaCl**

Cultivations were performed as mentioned by Steil *et al.* (2003) [80]. Briefly, *B. subtilis* was grown for 24 h on a LB agar plate at 37°C and used to inoculate 100 mL of Spizizen's minimal medium (SMM) media containing 1.2M NaCl in a 500 mL-Erlenmeyer bacterial culture flasks. The flasks were aerated overnight by shaking at 220 RPM at 37°C in an orbital shaker (Innova 4230, New Brunswick, USA). A pre-culture of fresh 100 mL 1.2 M NaCl-SMM was inoculated to an OD<sub>578</sub> of 0.1 with the overnight cultures. After these pre-culture reached an OD<sub>578</sub> of 1.0 they were used to inoculate to a pre-warmed main culture of 100 mL SMM containing 1.2 M NaCl to a final OD<sub>578</sub> of 0.1. The growth curve was recorded and samples for RNA isolation were harvested (as described in section 4.7) at OD<sub>578</sub> 1.0.

#### 4.4.3 Growth at 16°C

Cultivations were performed according to Budde *et al.* 2006 [118]. Briefly, *B. subtilis* was grown for 24 h on a LB plate at 37°C and used to inoculate 100 mL of overnight Spizizen's minimal medium (SMM) in a 500 mL-Erlenmeyer bacterial culture flasks. The flasks were aerated by shaking at 220 RPM at 37°C in an orbital shaker (Innova 4230, New Brunswick, USA). A fresh 100 mL SMM (pre-culture) was inoculated to an optical density (OD) of 0.1 at 578 nm from the overnight cultures. After the pre-cultures reached an OD<sub>578</sub> of 0.5, a 100 mL of pre-cooled (16°C) SMM main culture were inoculated to a final OD<sub>578</sub> of 0.1. The main cultures were grown at 16°C at 220 rpm in an orbital shaker. The growth curve was recorded and samples for RNA isolation were harvested (as described below in section 4.7) at OD<sub>578</sub> 1.0.

#### 4.4.4 Growth at 51°C

Cultivations were performed as mentioned by Holtmann *et al.* (2004) [119]. Briefly, *B. subtilis* was grown for 24 h on a LB plate at 37°C and used to inoculate 100 mL of overnight Spizizen's minimal medium (SMM) in a 500 mL-Erlenmeyer bacterial culture flasks. The flasks were aerated by shaking at 220 RPM at 37°C in an orbital shaker (Innova 4230, New Brunswick, USA). A fresh 100 mL SMM (pre-culture) was inoculated to an optical density (OD) of 0.1 at 578 nm from the overnight cultures. After the pre-cultures reached an OD<sub>578</sub> of 0.5, a 100 mL of pre-warmed (51°C) SMM main culture were inoculated to a final OD<sub>578</sub> of 0.1. The main cultures were grown by shaking at 160 linear strokes/minute (stroke length 18cm) at 51°C in a water bath (OLS 200, Grant Instruments. Cambridge Ltd.). The growth curve was recorded and samples for RNA were harvested (as described in section 4.7) at OD 1.0.

#### 4.4.5 Growth in M9

*B. subtilis* 168 Trp<sup>+</sup> was grown in 5 mL of LB for 4 hours at 37°C and used to inoculate 100 mL of overnight culture with three different dilutions (1:10000, 1:20000, 1:40000). These overnight cultures were allowed to grow for 12 to 14 hours at 37°C in an orbital shaker at 300 rpm of vigorous shaking (to avoid oxygen limitation during stationary phase). From the overnight cultures, an exponentially growing culture was used to inoculate the 200 mL of main culture to a final OD at 600nm of 0.05. The main culture was allowed to grow and three samples for RNA were harvested to reflect three growth states of the growth curve, they are exponential phase (OD<sub>600</sub> at 0.4), early stationary phase (at OD<sub>600</sub> 1.3 which is approximately 90 min after exponential phase) and late stationary phase (at OD<sub>600</sub> at 1.0 which is approximately 180 min after entry into stationary phase).

## 4.5 EXPERIMENTS FOR OPTIMIZING TRYPSIN DIGESTION OF PROTEIN SAMPLES FROM SPORULATING *B. SUBTILIS*

### 4.5.1 Growth in DSM media

Exponentially growing *B. subtilis* was inoculated to DSM (Difco Sporulation Medium) to an optical density (OD) of 0.1 at 600 nm and the flasks were aerated by shaking at 220 RPM at 37°C in an orbital shaker (Innova 4230, New Brunswick, USA). Samples for protein isolation and heat kill assay were harvested by taking equivalent volume for 15 OD units starting at exponential phase ( $OD_{600nm} - 1$ ) followed by every hour until 6 hours into stationary phase.

### 4.5.2 Calculation of percentage of heat resistant endospores (heat kill assay)

Frequency of heat resistant endospore formation was calculated from the number of CFU's (colony forming units) before and after heat treatment (20 min at 80°C), which was determined by plating various dilutions ( $10^{-5}$ ,  $10^{-6}$  &  $10^{-7}$ ) on agar plates. Non-heated samples with the same dilutions were considered as the controls and were set as 100% of CFU's.

## 4.6 CHEMOSTAT BASED CULTIVATIONS (PERFORMED BY MICHAEL KOHLSTEDT, BRAUNSCHWEIG)

All experiments were performed with the tryptophan prototroph wild-type *B. subtilis* 168 Trp<sup>+</sup> [13]. Cells from glycerol stocks were grown overnight on LB agar plates composed of: 10 g L<sup>-1</sup> tryptone, 10 g L<sup>-1</sup> NaCl, 5 g L<sup>-1</sup> yeast extract and 15 g L<sup>-1</sup> agar. Subsequently a single colony was transferred into a 500-mL baffled shake flask filled with liquid LB medium. After 2 hours cells were harvested via centrifugation, washed with deionized water and transferred into M9 minimal medium supplemented with 3,4-dihydroxybenzoic acid as chelating agent and grown up to an optical density of 1. The M9 medium contained: 5 g L<sup>-1</sup> glucose, 8.5 g L<sup>-1</sup> Na<sub>2</sub>HPO<sub>4</sub>·2H<sub>2</sub>O, 3 g L<sup>-1</sup> KH<sub>2</sub>PO<sub>4</sub>, 1 g L<sup>-1</sup> NH<sub>4</sub>Cl, 0.5 g L<sup>-1</sup> NaCl, 246 mg L<sup>-1</sup> MgSO<sub>4</sub>·7H<sub>2</sub>O, 30 mg L<sup>-1</sup> 3,4-dihydroxybenzoic acid, 14.7 mg L<sup>-1</sup> CaCl<sub>2</sub>·2H<sub>2</sub>O, 13.5 mg L<sup>-1</sup> FeCl<sub>3</sub>·6H<sub>2</sub>O and 10 mL of a trace element solution with the following components: 0.17 g L<sup>-1</sup> ZnCl<sub>2</sub>, 0.1 g L<sup>-1</sup> MnCl<sub>2</sub>·4H<sub>2</sub>O, 0.06 mg L<sup>-1</sup> CoCl<sub>2</sub>·6H<sub>2</sub>O, 0.06 mg L<sup>-1</sup> Na<sub>2</sub>MoO<sub>4</sub>·2H<sub>2</sub>O and 0.043 g L<sup>-1</sup> CuCl<sub>2</sub>·2H<sub>2</sub>O. Precultured cells served as inoculum for 4 simultaneous bioreactor cultivations in a parallel 1 L bioreactor system (dasGIP, Jülich, Germany) with a working volume of 300 mL of M9 minimal medium each with the same composition as described above but with only 1 g of glucose per liter. In the 4<sup>th</sup> reactor naturally labeled glucose was replaced by >99% [1-<sup>13</sup>C]-glucose (Euriso-top, Gif sur Yvette, France) for metabolic flux analysis. The cultivation was started in batch mode and before substrate depletion chemostat mode was initiated by starting feed and harvest pumps at a fixed pump rate of 30 mL h<sup>-1</sup> to keep the reactor volume and the growth rate of 0.1 h<sup>-1</sup> constant. Aeration rate, agitation speed, temperature and pH were kept constant at 0.5 vvm, 1,000 rpm, 37°C and 7.1 respectively. Offgas CO<sub>2</sub> formation was monitored by a mass spectrometer (Pfeiffer Vacuum, Asslar, Germany). Chemostat cultures were run until metabolic and isotopic steady-state were reached which was defined as at least 5 volume changes, as well as stable

optical density, CO<sub>2</sub> exhaust gas concentration and an invariant extracellular metabolite profile. When steady-state was reached, sampling for transcriptome, metabolome, proteome and fluxome analysis was performed at the same time.

#### 4.7 SAMPLE HARVESTING FOR TRANSCRIPTOME ANALYSIS

Sample harvesting and RNA extraction was performed as previously described (Eymann et al, 2002 [29]). Briefly, 15 optical density units (OD units) of cells were harvested by centrifugation (6,700 x g, 10 min, 4 °C) after addition of ½ volume of frozen killing buffer (20 mM Tris-HCl adjusted to pH 7.5, 5 mM MgCl<sub>2</sub>, 20 mM NaN<sub>3</sub>) to the culture sample. After discarding the supernatant, the obtained cell pellets were frozen in liquid nitrogen for RNA extraction.

#### 4.8 RNA PREPARATION

##### Lysis solution:

<b>guanidine-thiocyanate (4 M)*</b>	118.16 g

<b>10 % N-lauroylsarcosinate (0.5 %)**</b>	12.5 mL
<b>deionized water.</b>	ad 250 mL

##### Killing buffer:

<b>Tris-HCl, pH-7.5 (Stock solution: 1 M)***</b>	20 mM
<b>MgCl<sub>2</sub> (Stock solution: 1 M)**</b>	5 mM
<b>NaN<sub>3</sub> (Stock solution: 2 M)*</b>	20 mM

\*Merck. Darmstadt, \*\*Roth. Lauterbourg, \*\*\*Sigma –Aldrich.

Bacterial cell pellets were resuspended in 200 µL of ice cold killing buffer and flash frozen using liquid nitrogen cooled Teflon vessels. Then, the Teflon vessels were closed with the disruption ball and frozen in liquid nitrogen for 1 min and were then subjected to mechanical shaking at 2600 rpm for 2 min in a bead mill (Mikrodismembrator S, B. Braun Biotech International GmbH, Melsungen, Germany). The resulting lysate was resuspended in 4 mL lysis buffer by repeated pipetting and then aliquoted at 1 mL each to a 2 mL microcentrifuge tubes which were flash frozen in liquid nitrogen. Acid phenol (Roth, Lauterbourg) was added to the frozen lysate in a 1:1 ratio and mixed on a thermomixer (Eppendorf, Germany) until completely thawed, and then for additional 5min. Organic and aqueous phase were separated by centrifugation (12000 x g, 15 min RT) and the supernatant (maximum 850 µL) was carefully transferred (without disturbing DNA and protein containing interphase) into a fresh microcentrifuge tube. To the

supernatant collected, one volume of acid phenol was added and then mixed on a thermomixer and centrifuged (12000 x g, 15 min). The resultant supernatant (maximum 700 µL) was again transferred into a fresh microcentrifuge tube to which equal volume of chloroform/IAA was added, mixed and centrifuged as above mentioned. Supernatant was transferred into a fresh microcentrifuge tube to which 1/10 volume of 3 M Na-Acetate, pH-5.2 and 1 mL of isopropanol was added, mixed well and the RNA was precipitated overnight at -20°C. After centrifugation (15000 x g 15 min) the resultant supernatant was discarded and the RNA pellet was washed with 70% ethanol and the pellet was vacuum dried (LTF Labortechnik, Germany). The RNA pellet was dissolved in an appropriate volume (50-100 µL) of nuclease-free water (Ambion Inc., Austin, TX, USA, now part of Applied Biosystems, Foster City, CA, USA) for 3 hours on ice and then for 30 min at room temperature.

The concentration was determined photometrically (NanoDrop ND-1000, NanoDrop Technologies, Wilmington, DE, USA), and the RNA quality was checked with an Agilent-Nano chip on an Agilent 2100 Bioanalyzer (Agilent Technologies, Santa Clara, CA, USA).

For further processing of RNA for microarray hybridization, RNA had to be pure without DNA contamination. For this reason DNase treatment was performed and RNA was purified using the RNA Clean-Up and Concentration Kit (Norgen Biotek Corp., Thorold, ON, Canada; distributed by BioCat GmbH, Heidelberg, Germany). The concentration after cleanup was determined photometrically, and the quality was checked again with an Agilent 2100 Bioanalyzer.

The purified mRNA was used for the subsequent gene expression profiling for either relative expression profiling with Agilent customized microarray or with NimbleGen Tiling array technology (see below).

## 4.9 GENE EXPRESSION PROFILING

Two different kinds of gene expression profiling were performed in this study, they are relative gene expression profiling (Agilent customized microarray) and intensity based high density Tiling array (NimbleGen Tiling array)

### 4.9.1 Relative gene expression analysis

Relative gene expression analysis was performed by the dual dye hybridization method, where mRNA of the samples of interest was hybridized against the mRNA of a reference pool. The reference pool was prepared by mixing equal amounts of mRNA from all samples in the corresponding experiment.

<b><u>Chemicals</u></b>	<b><u>Company</u></b>
<b>Random Primer</b>	Promega
<b>Agilent Two-Color RNA Spike-In Kit</b>	Agilent
<b>dNTPs</b>	Roche

<b>Cy5-dCTP</b>	GE Healthcare
<b>Cy3-dCTP</b>	GE Healthcare
<b>CyScribe GFX Purification Kit</b>	GE Healthcare
<b>Superscript II</b>	Invitrogen
<b>RNase H</b>	Invitrogen
<b>Gene Expression Hybridization Kit</b>	Agilent
<b>Gene Expression Wash Buffer 1</b>	Agilent
<b>Gene Expression Wash Buffer 2</b>	Agilent
<b>Hyb Gasket Slides , 4 arrays per slide</b>	Agilent

10 µg (20.5 µL) of resultant RNA with high purity and quality was mixed with 2.5 µL of random primers and 1 µL of each Spike-Mix A to the reference (pool) and Spike-Mix B to the sample. The tubes were incubated at 70°C (heat block) for 10 min and then on ice for 5 min, 22.5 µL of master mix(mentioned below) and 1.25 µL of Cy3(for reference pool) and Cy5(for sample) was added and mixed well(these steps are performed in low light as Cy-dyes are light sensitive). Reverse transcription was done by adding 2 µL of superscript-II to the above solution and incubated for 42°C (60 min), then at 70°C (for 10min) and then onto ice (5 min, all the incubations were performed in the dark). After the cDNA was synthesized, remaining RNA was degraded by adding 1 µL of RNaseH (room temperature, 30min).

#### Master mix composition

	<b>1X (for one reaction)</b>
<b>Nuclease-free water</b>	7 µL
<b>5x 1st Strand Buffer</b>	10 µL
<b>0.1 M DTT</b>	5 µL
<b>10 mM dNTP Mix, 2.5 mM dCTP</b>	0.5 µL

The resultant cDNA was purified by CyScribe GFX purification kit, cDNA concentration and Cy-Dye concentration were measured with a NanoDrop. The incorporation rate of the Cy-dyes was calculated with the following formula:

$$\text{Incorporation rate} = 1000 * \text{concentration of Cy3 (or) Cy5} / \text{concentration of cDNA}$$

0.4 µg of Cy3-labelled cDNA and 0.4 µg of Cy5-labelled cDNA were mixed and total volume was adjusted to 44 µL with nuclease-free water and incubated at 95°C for 2 min and then placed onto ice. 11 µL of preheated (60°C, 30 min) 10x blocking agent and 60 µL of 2x GEx Hybridization buffer were added to the cDNA mix and centrifuged at 13000 x g for 1min. 100 µL of the mix was added on the Agilent gasket slide and combined together with microarray slide with the help of an Agilent hybridization chamber. Hybridization was performed for 17 hours at 65°C in an Agilent hybridization oven.

After hybridization, non-specific probes were removed by washing with Agilent wash buffers according to the manufacturer's guidelines. Scanning was performed with a Agilent Technologies Scanner G2505C US45103079 in accordance with "Two-Colour Microarray-based Gene Expression Analysis manual, version 5.5"

Data were extracted and processed using the Feature Extraction software (version 9.5, Agilent Technologies). For each gene on the microarray, the error-weighted average of the log ratio values of the individual probes was calculated using the Rosetta Resolver software (version 7.2.1, Rosetta Biosoftware).

---

#### 4.9.1.1 Data analysis – relative gene expression analysis

---

A reference pool was prepared by mixing equal amounts of RNA isolated from each of the samples in the experiment. The individual samples of interest were labeled with Cy5, whereas the reference pool was labeled with Cy3, equal amounts of Cy5 and Cy3 labeled cDNA were hybridized onto an Agilent custom microarray. For each gene on a microarray, the error-weighted average of the log ratio (Cy5/Cy3) values of the individual probes was calculated using the Resolver software (version 7.2.1, Rosetta Biosoftware, Seattle, USA). As this is dual dye hybridization, the common reference pool was used for experimental normalization to reduce the influence of technical errors within the experiment. The normalized ratio data represent the relative gene expression levels for the corresponding sample and these data were imported into the software Genedata Analyst for the subsequent analysis.

---

#### 4.9.2 Tiling array design

---

The “BaSysBio *Bacillus subtilis* T1 385K” array was designed by Hanne Jarmer (Center for Biological Sequence Analysis, Department of Systems Biology, Technical University of Denmark, Lyngby, Denmark) using the OligoWiz software and parameters which have recently been published (Rasmussen *et al.*, 2009 [93]). The sequences were synthesized on quartz wafers by NimbleGen (Roche NimbleGen, Madison, WI, USA) in a custom, high-density DNA array format.

---

##### 4.9.2.1 Tiling array hybridization

---

The tiling array hybridization was performed at NimbleGen (Roche NimbleGen, Madison, WI, USA) according to the company’s standard operating protocols. Briefly, 10 µg of high quality RNA samples were reverse transcribed to cDNA in the presence of actinomycin D with subsequent alkaline RNA hydrolysis. Precipitated and resolved cDNA was labeled with Cy3 dye via NHS-Ester Dye Coupling Reaction. After spin-column based purification and quality control, labeled cDNA was hybridized together with appropriate controls to tiling arrays “BaSysBio Bsub T1 array” [93, 116]. Arrays were washed and scanned and raw intensity data of tiling probes were provided to us for the data analysis.

---

#### 4.9.2.2 Tiling array raw data analysis

---

The raw data analysis and condensing of probe data to transcripts/genes was performed by Pierre Nicolas, Aurélie Leduc, and Philippe Bessi res (INRA, Math matique Informatique et G nome, Jouy-en-Josas, France). Intensity values for annotated genes were derived from the individual probe data by calculating the median of the probes located within the genomic coordinates of these genes. These intensity values were uploaded to Genedata Analyst for further statistical analysis and functional categorization.

---

#### 4.9.3 Statistical and functional data analysis in Genedata Analyst

---

Relative gene expression data (normalized ratio data) obtained from the Agilent microarrays were used for ratio building against the respective control samples in the corresponding experiments. Significantly regulated genes after a statistical cut-off of three fold change (with a p-value of 0.01 after Benjamini-Hochberg correction) were used for performing K-means clustering and Fisher's exact test in Genedata Analyst. Functional gene categorization was obtained from SubtiWiki (<http://SubtiWiki.uni-goettingen.de/wiki/index.php/Categories>) and Fisher's exact test for the functional class enrichment was performed in Genedata Analyst.

The intensity data obtained from Tiling array was subjected to median normalization and then normalized to the respective control points. Other statistical tests were performed in a similar manner as mentioned earlier.

---

### 4.10 PROTEIN ISOLATION AND ESTIMATION

---

---

#### 4.10.1 Sample harvesting and preparation of protein lysate by cell disruption

---

Protein extracts from frozen pellets were prepared and protein concentrations were determined as described earlier [120, 121]. In short, during the experiment an equivalent volume of 10 or 12 optical density units (OD units) of the bacterial culture was harvested by centrifugation at 8000 rpm for 5 min at 4 C. The supernatant was discarded. After washing the pellets with 10 mL of TE-buffer (20 mM Tris, 10 mM EDTA, pH 8) pellets were stored at -70 C or immediately used for cell disruption. Frozen pellets were resuspended in 500  L of ice cold TE-buffer and added to a 2 mL vial (Sarstedt) prefilled with 500  L of unwashed glass beads (160  m, Sigma Life sciences). Cell disruption was performed by ribolysing (Fast prep-120, BIO 101 Thermo Scientific) for 30 s at 6.5 m/sec speed and then on ice for 5 min. This was repeated for two more times (repetition ensured the disruption efficiency to be 99-99.9% complete) followed by centrifugation at 13000 g (10 min, 4 C). Resultant supernatants were transferred to a new 1.5 mL microcentrifuge tube avoiding carryover of glass beads and centrifuged at 13000 g (30 min, 4 C). This process was repeated once again to remove remaining glass beads and cell debris.

#### 4.10.2 Determination of protein concentrations by Ninhydrin assay

Ninhydrin (2,2-Dihydroxyindane-1,3-dione) reagent is commonly used to detect ammonia or primary and secondary amines. Protein estimation using Ninhydrin was performed according to Starcher *et al.*, 2001 [121]. A calibration curve using BSA (10 mg/mL in TE buffer) was prepared with different concentrations ranging from 0.25 µg/µL to 10 µg/µL. Protein concentration was estimated for samples as mentioned below.

Calibration curve BSA\* (10 mg/ mL in TE buffer)

0,25 µg/µL	BSA 2,5 µL BSA + 97,5 µL H <sub>2</sub> O**	100 µL 12 N HCl*
0,5 µg/µL	BSA 5,0 µL BSA + 95,0 µL H <sub>2</sub> O**	
1,0 µg/µL	BSA 10,0 µL BSA + 90,0 µL H <sub>2</sub> O**	
1,5 µg/µL	BSA 15,0 µL BSA + 85,0 µL H <sub>2</sub> O**	
2,0 µg/µL	BSA 20,0 µL BSA + 80,0 µL H <sub>2</sub> O**	
4,0 µg/µL	BSA 40,0 µL BSA + 60,0 µL H <sub>2</sub> O**	
6,0 µg/µL	BSA 60,0 µL BSA + 40,0 µL H <sub>2</sub> O**	
8,0 µg/µL	BSA 80,0 µL BSA + 20,0 µL H <sub>2</sub> O**	
10,0 µg/µL	BSA 100,0 µL BSA	20µL 12 N HCl
Samples	20µL protein extract	

\*Sigma, \*\*Baker HPLC Water, \*\*\*Roth

All the tubes were incubated for 24 hours at 100°C for acid hydrolysis. Ninhydrin reagent was freshly prepared, mixed for 1hour and stored in the dark.

<b>Ninhydrin*</b>	<b>1g in 38.75 mL ethylene glycol*</b>
<b>4 N sodium acetate buffer(pH 5.5)</b>	<b>12,5 mL</b>
<b>Stannous chloride**</b>	<b>50 mg</b>

\*Roth, \*\*Sigma,

Hydrolyzed proteins (BSA and samples) were diluted 1:100. 400 µL of H<sub>2</sub>O was added to 200 µL of diluted proteins and 600 µL of ninhydrin reagent was added and incubated for 10 min at 100°C (in the dark). Measurement of OD was done at 575 nm on a spectrophotometer (Ultrospec 2100 pro, GE HealthCare) using appropriate blanks.

#### 4.10.3 Determination of protein concentrations by Bradford assay

The concentration of proteins in aqueous solutions was determined according to Bradford [122]. Quantification is based on a shift of the absorption maximum of the dye Coomassie Brilliant Blue from 465 nm to 595 nm when the dye binds to proteins (to the hydrophobic amino acids). For the estimation of protein concentrations the ready-to-use Protein Assay Reagent (Bio-Rad) was used in a ratio of 1:5. Protein concentrations of unknown samples were determined from a calibration curve of BSA in concentrations ranging from 1 to 12 µg/µL.

## 4.11 PROTEOLYSIS AND PURIFICATION OF PROTEOME SAMPLES

### 4.11.1 Proteolysis by trypsin

Disulfide bonds in 2  $\mu$ g of protein from each sample were initially reduced by addition of 25 mM DTT prepared in 20 mM ammonium bicarbonate and incubated at 60°C for 1 h. Following reduction, the protein samples were carbamidomethylated with 100 mM iodoacetamide in 20 mM ammonium bicarbonate and incubated at 37°C in dark. After 30 min, protein samples were subjected to proteolysis using trypsin (Promega) overnight (16 h) in a ratio of 1:25 (trypsin:protein). 1% acetic acid was added to stop the proteolysis. Digested peptides were then desalted to remove the impurities that might interfere with MS analysis.

### 4.11.2 Purification and in-gel digestion of the proteins

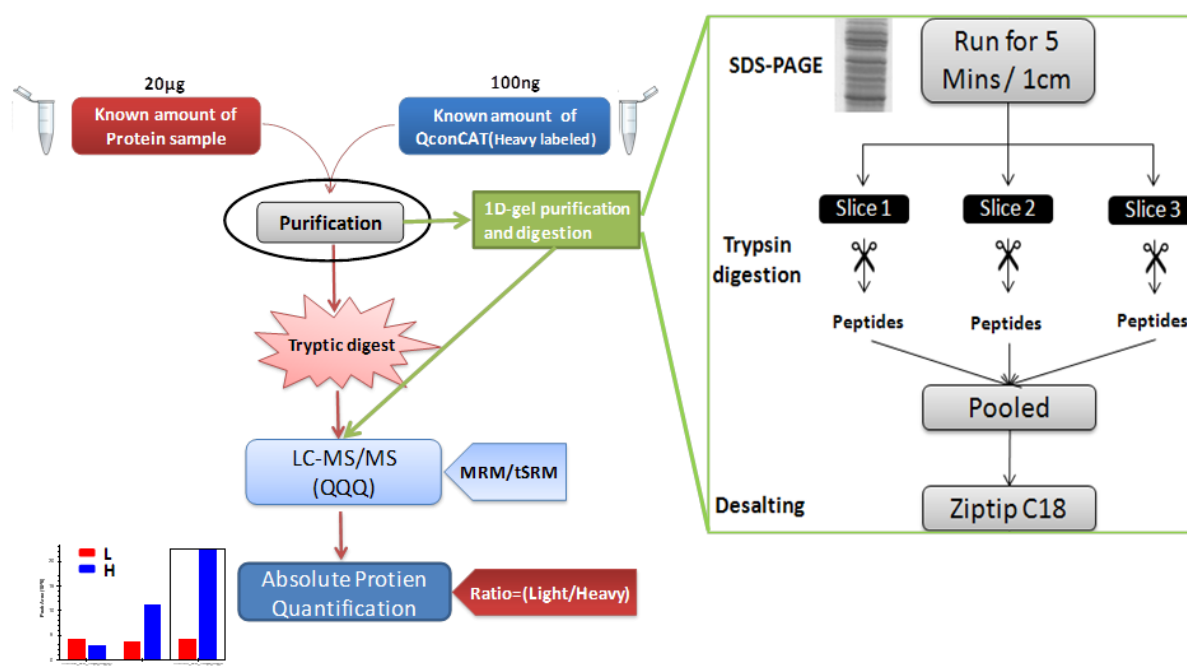

Figure 6: Schematic representation of sample preparation, purification, trypsin digestion and MRM analysis. Inset – 1D-gel based purification of proteins and in-gel trypsin digestion which is required for the samples harvested from fermentation and chemostat cultivations.

Protein samples obtained from different sources like fermentation and Chemostat cultivation tend to contain some impurities that might interfere with trypsin digestion. So, proteins were purified prior to digestion when necessary. In order to purify the protein extracts, 15  $\mu$ g of protein lysate and a defined amount of QconCAT were applied to a NuPAGE® Bis-Tris Gels 4-12% (Life Technologies Corporation- Carlsbad, California). Separation, staining and destaining were carried out according to the manufacture guidelines except for the run time. The run was stopped exactly after 5 min which allowed the sample to be separated for 1 cm. Each lane was sliced into three pieces which were processed independently (Figure 6). Gel pieces were washed twice with 200  $\mu$ L of 20 mM ammonium bicarbonate in 50% (v/v) acetonitrile (ACN) for 30 min

at 37 °C. Thereafter the gel pieces were dehydrated by two times washing with 200 µL of ACN for 15 min. Trypsin solution (20 ng/µL trypsin in 20 mM ammonium bicarbonate) was added until the gel pieces stopped swelling. Digestion was allowed to proceed for 16–18 h at 37 °C. Peptides were extracted from the gel pieces with 40 µL of 0.1% (v/v) acetic acid by incubation in an ultrasonic bath for 30 min, followed by a second extraction with 40 µL of 50% ACN in 0.05% acetic acid. The peptide containing supernatants of each band were collected and pooled for each lane; excess liquid was removed by lyophilization. The resulting peptide mixtures were resuspended in 100 µL of buffer A (0.1% acetic acid, 2% ACN) and purified using C18-ZipTip columns (Millipore, Bedford). 300 ng of the purified peptide mixture was used for subsequent MS analysis.

---

#### 4.11.3 Desalting of peptides by ZipTip®

---

Peptides derived from tryptic digestions were purified and desalted using C18 resin-ZipTip® pipette tips (Millipore). ZipTip columns were equilibrated by serial pipetting of 100% ACN; 80% ACN in 1% AA; 50% ACN in 1% AA; 30% ACN in 1% AA, and 1% AA. Then the peptides were loaded onto the ZipTip by pipetting 20 times. ZipTip was washed 5 times with 1% AA and peptides were eluted in 50% ACN+1% AA and 80% ACN+1% AA. Eluates were pooled and ACN was removed by vacuum centrifuge concentrator (Eppendorf). Peptides were dissolved in Buffer A (2% ACN, 0.1% AA) to a final concentration of 100 ng/µL and stored at -20°C until MS measurement.

---

### 4.12 MASS SPECTROMETRY

---

---

#### 4.12.1 MS parameters –LTQ Velos Orbitrap

---

LC-MS/MS was performed on a Proxeon nano-LC system connected to an LTQ-Velos-Orbitrap-MS (Thermo Scientific) equipped with a nano-ESI source. For liquid chromatography separation an Acclaim PepMap 100 column (C18, 3 µm, 100 Å) capillary of 15 cm bed length was used. The flow rate used was 300 nL/min for the nano column and the solvent gradient used was from 0% solvent B to 25% solvent B in 60 min). Solvent A was 0.1% AA, whereas aqueous 90% ACN in 0.1% AA was used as solvent B. The MS was operated in the data-dependent mode to automatically switch between Orbitrap-MS and LTQ-MS/MS acquisition. Survey full scan MS spectra (from m/z 300 to 2,000) were acquired in the Orbitrap with resolution  $R = 60,000$  at m/z 400 (after accumulation to a target of 1,000,000 charges in the LTQ) allowed sequential isolation of the most intense ions, up to five, depending on signal intensity, for fragmentation on the linear ion trap using collision induced dissociation at a target value of 100,000 charges. Target ions already selected for MS/MS were dynamically excluded for 60 seconds. General MS conditions were: electrospray voltage, 1.5 kV; no sheath and auxiliary gas flow. Ion selection threshold was 500 counts for MS/MS, and an activation Q-value of 0.25 and activation time of 30 ms were also applied for MS/MS.

---

#### 4.12.2 MS parameters –TSQ Vantage

---

Peptide separation was carried out using a Acclaim PepMap 100 column (C18, 5  $\mu$ m, 100 Å, 15 cm bed length, Dionex) and applying a binary gradient from 0% to 30% buffer B(100% acetonitrile [v/v], 0.1% acetic acid [v/v]) in 60 min and to 40% buffer B in additional 10 min and to 90% buffer B in additional 10 min at a flow rate of 300 nL min<sup>-1</sup> on an online Proxeon nano-LC system (Proxeon, Odense, Denmark).

For MRM, LC-MS/MS experiments were performed on a triple quadrupole mass spectrometer (TSQ Vantage, Thermo Scientific) operated in nano-electrospray mode. For ionization 1600 V-1800 V of spray voltage and 250 °C of capillary temperature were used. The selectivity for both Q1 and Q3 were set to 0.7 Da (FWHM-full width half maximum). The collision gas pressure of Q2 was set at 1.5 mTorr. TSQ Vantage was operated in SRM mode and data acquisition was done in scheduled SRM manner.

---

#### 4.12.3 Data analysis

---

Qualitative and relative quantitative (when required) analysis of the MS data was performed with Rosetta Elucidator. The frame and feature annotation was done using the following parameters: retention time minimum cut-off 11 min, retention time maximum cut-off 78 min, m/z minimum cut-off 300 and maximum 1,700 m/z. An intensity threshold of 1,000 counts, an instrument mass accuracy of 10.0 ppm, and an alignment search distance of 4.0 min were applied for binning process. For identification, the *B. subtilis* Uniprot 12.7 forward and reverse FASTA sequence (downloaded from Uniprot) in combination with SEQUEST was used. Oxidation of methionine was set as variable modification and carbamidomethylation of cysteine as static modification. Proteins were considered for further investigation when at least one or more peptides were identified in at least one experiment and p-value less than 0.05.

The relative intensities for the proteins were then imported to Genedata Analyst from Rosetta Elucidator and further data analysis was performed. “Median normalization relative to one” was performed on each of the sample. The final normalized relative intensities were then log transformed and then appropriate controls were chosen for the “control point normalization” used for the further investigation.

Functional gene categorization was obtained from SubtiWiki (<http://SubtiWiki.uni-goettingen.de/wiki/index.php/Categories>). Fisher’s exact test for the functional class enrichment was performed using the SubtiWiki classification performed in Genedata Analyst.

## 4.13 ABSOLUTE PROTEIN QUANTIFICATION BY MULTIPLE REACTION MONITORING (MRM)

### 4.13.1 Design of the QconCATs

Tryptic proteotypic peptides of all the proteins under investigation were selected based on the previous in-house acquired MS data. This peptide list was refined based on the set of rules indicated by Pratt *et al.* (2006) [102]. At least three peptides per protein were finally selected and the list was provided to PolyQuant GmbH, (Bad Abbach Germany) where the synthesis and labeling of QconCATs (concatemers of Q peptides) were performed. In brief, the Q peptides were aligned in a mixed fashion and a complementary gene was synthesized and inserted into a vector, which was later introduced into a heterologous expression system for protein production. The QconCAT proteins were expressed in *Escherichia coli* and were labeled with stable isotopes by growth in the presence of stable isotope-labeled precursors (C13 & N15). The labeled QconCAT proteins were then purified with the help of polyhistidine-tag [123] and quantified. The purified QconCATs were spiked to complex protein mixtures in defined amounts (as described in Figure 6). In general, tryptic digestion of the QconCAT-analyte mix releases each of the QconCAT peptides in a strict stoichiometry of 1:1 unless there is a missed cleavage.

### 4.13.2 MRM method development

Initially 30 fmol QconCAT protein was digested with trypsin and analyzed using the LTQ-Velos Orbitrap. Proteins were identified via automated SEQUEST[124] search (Sorcerer built 4.04, Sage-N Research Inc., Milpitas, CA, U.S.A.) in integration with TPP (trans proteomic pipeline [125] against a customized databases containing fasta sequences of QconCATs with a mass tolerance of 10 ppm and allowing up to two missed tryptic cleavages as search criteria.

The resultant mzXML and pepXML(peptide sequence assignments of MS/MS scans) files from TPP workflow were used as a spectral library for the software Skyline 1.1 (MacCoss Lab Software)[126]. Appropriate precursor charge state and eight ideal y-type product ions for each peptide were selected for generating an initial test MRM method. With these initial details, a test MS analysis was performed with tryptic digest of 30 fmol of QconCAT and the results were analyzed with the Skyline software. Top four intense transitions for each peptide were then selected for collision energy optimization in accordance with MacLean *et al.* 2010[127]. In the current study optimization of collision energy resulted in 20% signal gain over all peptides tested. The signal gain was more prominent for those peptides that were +3 charged compared to +2 charged peptides. A final method with optimized collision energy and recorded retention time window (five minutes) was generated and this method was used to analyze the complex sample spiked with defined amount of QconCAT. For each peptide three or four product ions were chosen and all the parameters were then applied for both the heavy and light peptides. Complete method used for the targeted analysis was shown in Table 1.

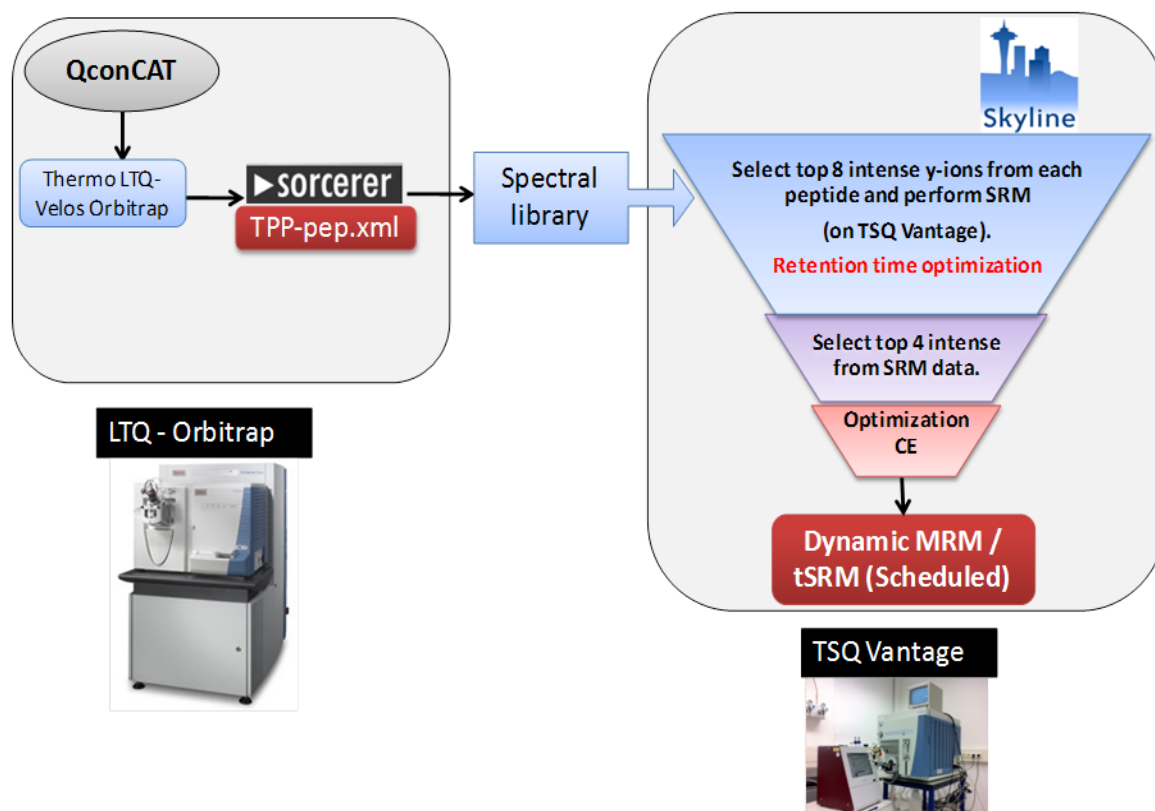

Figure 7 : Workflow representing the method development for MRM based absolute quantification. Transfer of the information from LTQ-Orbitrap measurements to the TSQ Vantage via TPP-pep.xml and subsequent retention time recording and collision energy optimization for the final MRM method.

**Table 1: \* MRM method summary. Peptides used for the quantification of the proteins: Description of the used peptide information in the following format "Peptide\_PeptideCharge\_Product ion\_Product Charge. Endogenous peptide end with the suffix "L" and heavy peptides as the internal standard for quantification end with suffix "H". CE – optimized collision energy.**

**4.14 ENZYME ACTIVITY ASSAYS** (PERFORMED BY MICHAEL KOHLSTEDT, BRAUNSCHWEIG)

---

For determination of phosphoglucosomerase activity, cells were disrupted in a bench top homogenizer (MP Biomedicals, Santa Anna, USA) in 100 mM Tris/HCl (pH 7.8) containing 10 mM MgCl<sub>2</sub>. Activity was quantified using glucose 6-phosphate dehydrogenase (G6PDH) as coupling enzyme and online monitoring of NADPH formation at 340 nm. The assay was performed at pH 7.8 with 100 mM Tris/HCl, 10 mM MgCl<sub>2</sub>, 0.5 mM NADP, 1.25 U G6PDH, 4 mM fructose 6-phosphate and 20 µL crude cell extract. Cell disruption and activity measurement for isocitrate dehydrogenase were also carried out in 100 mM Tris/HCl (pH 7.8) containing 10 mM MgCl<sub>2</sub>. The reaction mix for determination of enzyme activity additionally contained 1 mM isocitrate, 0.5 mM NADP and 25 µL of crude cell extract.

---

**4.15 METABOLOME ANALYSIS** (PERFORMED BY HANNA MEYER, GREIFSWALD)

---

Samples for intracellular metabolome analysis were obtained by fast vacuum dependent filtration [128]. A pre-cooled (-20°C) upper part of the filtration system (funnel, filter base) was used for sampling. For sampling, 10-20 OD units of the main culture were poured into a 50 mL falcon tube and cooled with liquid nitrogen for 30 s (sample temperature after cooling 9±2°C), by dipping falcon tube periodically in and out of the N<sub>2</sub> and shaken carefully in between (freezing should be avoided). The cooled culture was filtered (0.45 µm pore size, 47 mm, MilliPore, Schwalbach, Germany) and then quenched with 60% ethanol (w/v) (pre-cooled) and liquid nitrogen and were stored at -80°C until further treatment. For metabolite extraction and cell disruption, samples were thawed on ice (≤ 6°C) and the internal standards were added (20 nmol ribitol and norvaline for GC-MS and 2.5 nmol for LC-MS analysis). Afterwards samples were vortexed and shaken 10 times alternately and centrifuged for 5 min at 4°C at 15,500 g. The supernatant was transferred to a new falcon tube, while the pellet was once more extracted using cold water. The supernatants were combined and restocked with deionized water to a final organic solution concentration of 10% and stored at -80°C prior to lyophilization. Ion pairing-LC-MS measurement was performed using an Agilent HPLC System (1100 series, Agilent Technologies, Waldbronn, Germany) coupled to a Bruker micrOTOF mass spectrometer (Bruker Daltonics, Bremen, Germany) was operated in ESI negative mode using a mass range from 50 to 3000 m/z at a dry. Completely lyophilized samples were dissolved in 100 µL deionized water and centrifuged for 2 min (15,500 g, 4°C). The supernatants were transferred into glass vials with micro inserts for small volume injections (injection volume 25 µL). Chromatographic separation was performed using a RP-C18 AppliChrom OTU LipoMare column (3.5 µm, 150x4.6 mm, AppliChrom, Oranienburg, Germany) equipped with a C18 pre-column (Phenomenex, Aschaffenburg, Germany). The gradient flow rate was 0.4 mL min<sup>-1</sup> and the total data acquisition runtime was 40 min. The mobile phase was A: 5% methanol and 95% water, containing 10 mM tributylamine as ion-pairing reagent and 15 mM acetic acid for pH adjustment to pH 4.9 and B: (100% methanol. The gradient elution started with 100% A for 2 min, 0-31% B in 2 min, 31-50% B in 18.5 min, 50-60% B in 2.5 min, 60-100% B in 1 min, hold 100% B for 7 min, 100%-0% B in 1 min, and hold 10 min at 0% B. As MS source parameters a dry gas (N<sub>2</sub>)

flow rate of  $8.0 \text{ L min}^{-1}$ , a dry temperature of  $180^\circ\text{C}$ , a nebulizer pressure of 1.6 bar, a capillary voltage of 4,000 V and a capillary exit voltage of -150 V were used. Furthermore, the skimmer 1 was set to -50 V, the hexapole 1 to -25 V and the hexapole 2 to -24 V. The transfer time was 50  $\mu\text{s}$  and pre-pulse storage was 8.0  $\mu\text{s}$ . Reference masses of the Agilent “ESI-tune mix” for electrospray applications in negative mode were used for automated  $m/z$  calibration in each chromatographic run. Metabolite quantification was done by QuantAnalysis® (Bruker Daltonik, Bremen, Germany). Peak areas of extracted ions were normalized to the internal standard area of camphor sulfonic acid. For determination of the calibration equation, different concentrations of pure standards were measured and analyzed in the same manner. A polynomial regression of degree 2 with a  $1/x$  weighting was used as calibration equation. The computed metabolite concentrations were further normalized to the sample volume and related to the respective cell dry weight. GC-MS (quadrupole) analysis was performed using an Agilent DB-5ms column as described previously [129]. Completely lyophilized samples were derivatized for 90 min at  $37^\circ\text{C}$  with MeOX and 30 min at  $37^\circ\text{C}$  with MSTFA. After centrifugation for 2 min at room temperature the supernatant was transferred into GC-Vials prior to measurement. Metabolite quantification was done by the ChomaTOF® (LECO) software. Peak areas of extracted ions were normalized to the area of the internal standard ribitol. For determination of the calibration equation, different concentrations of pure standards were measured and analyzed in the same manner. Dependent on the precision of the calibration equation, calibration was done via a polynomial regression of degree 1 or 2 and a  $1/x$  weighting. The computed metabolite concentrations were further normalized to the sample volume and related to the respective cell dry weight. A volume of 4 mL of cell suspension was harvested via fast filtration (cellulose-nitrate,  $0.2 \mu\text{m}$  pore size, 47 mm, Sartorius, Göttingen, Germany) and washed as described previously [130]. Cell-containing filters were incubated (15 min,  $100^\circ\text{C}$ ) in caps containing 2 mL of  $200 \mu\text{M}$   $\alpha$ -aminobutyric acid as internal standard. Extracts were cooled on ice, transferred into 2 mL tubes and centrifuged (5 min,  $16,100 \text{ xg}$ ,  $4^\circ\text{C}$ ) to eliminate disrupted cells. Intracellular amino acids were then quantified via HPLC (Agilent Technologies, Waldbronn, Germany) applying OPA pre-column derivatization [131]. In order to quantify proline and cysteine, FMOC derivatization reagent, mercaptoethanol as reducing agent and iodoacetic acid to block sulfhydryl groups were also added to the sample. For extracellular metabolite measurement by  $^1\text{H-NMR}$ , a volume of 2 mL cell culture was rapidly filtrated through a syringe filter ( $0.2 \mu\text{m}$ , Sarstedt, Nümbrecht, Germany). The obtained supernatant was stored at  $-20^\circ\text{C}$ . Partial volume of the extracellular sample was buffered to pH 7.0 by addition of  $200 \mu\text{L}$  of a  $0.2 \text{ M}$  sodium hydrogen phosphate buffer (including  $1 \text{ mM}$  trimethylsilyl propanoic acid, pH 7.0) made up with  $50\% \text{ D}_2\text{O}$  to provide a nuclear magnetic resonance (NMR)-lock signal [132]. Spectral referencing was done relative to  $1 \text{ mM}$  sodium trimethylsilyl-[2,2,3,3- $\text{D}_4$ ]-1-propionic acid (TSP) in phosphate buffer. All NMR spectra were obtained at  $600.27 \text{ MHz}$  at a nominal temperature of  $310 \text{ K}$  using a Bruker AVANCE-II 600 NMR (Bruker Biospin GmbH, Rheinstetten, Germany). A modified 1D-NOESY pulse sequence was used with pre-saturation on the residual HDO signal during both the relaxation delay and the mixing time. A total of 64 free induction decays (FID scans) were collected using a spectral width of  $30 \text{ ppm}$  for a one-dimensional spectrum. Data analysis was implemented by AMIX (Bruker Biospin, Rheinstetten, Germany). The signal area of the internal standard TSP was used for direct quantification. A bicinchoninic acid-based protein assay kit (Thermo Fisher Scientific, Rockford, USA) was used for the determination of total extracellular protein in culture supernatant.

#### 4.16 <sup>13</sup>C METABOLIC FLUX ANALYSIS (PERFORMED BY MICHAEL KOHLSTEDT, BRAUNSCHWEIG)

Cell pellets were washed and hydrolyzed with 6M HCl for 24 h at 105°C. Obtained hydrolysates were transferred in centrifugal filter tubes (0.22 µm pore size, Ultrafree-MC, Millipore, Schwalbach, Germany) and centrifuged (1 min, 12.000 g) to filter off cell debris. Clear hydrolysates were dried under a constant nitrogen stream for 30 min at room temperature. Afterwards, derivatization of amino acids was carried out at 80°C in 50 µL dimethylformamide containing 0.1% pyridine and 50 µL N-methyl-N-t-butyltrimethylsilyl-trifluoroacetamide (MBDSTFA, Macherey-Nagel, Düren, Germany) for 30 min. Derivatized amino acids were separated by a 5975C GC and analyzed on a single-quadrupole 7890A MS with electron impact ionization (both Agilent Technologies, Waldbronn, Deutschland). In a first scan peaks were checked for quality (retention time, peak symmetry, no isobaric overlays, etc.). In a second more sensitive run only desired fragment ions (selected ion monitoring), containing the complete carbon backbone of the amino acid, were measured. Labeling information can be extracted from mass spectra and is corrected for naturally occurring isotopes. Macromolecular cell composition was reconstructed from previous biomass models of *B. subtilis* (Dauner & Sauer, 2001; Oh *et al.*, 2007), yielding building block requirements of anabolic precursor metabolites (G6P, F6P, R5P, E4P, GAP, 3PG, PEP, PYR, AcCoA, AKG, OAA). The cell composition further considered the potential influence of salt adaptation of *Bacillus* to high salinity, particularly cellular changes in protein and ion content, intracellular amino acid pools quantified in this study, as well as variations in cell wall fraction and composition under osmotic stress. López *et al.* observed an increase in cardiolipin content, an altered ratio of glyco- to phospholipids, as well as differences in fatty acid composition under salt stress. [133]. Metabolic fluxes were estimated using the open source software OpenFLUX [134]. The user-defined metabolic model is parsed into a MATLAB-readable model (Mathworks, Natick, USA). MATLAB subsequently estimates flux parameters using its non-linear constraint-based optimization algorithm FMINCON, an iterative least-square algorithm. Starting with a random initial set of fluxes, the algorithm computed the remaining dependent fluxes via stoichiometric mass balances, estimated the resulting labeling patterns of all compounds in the metabolic network for the given fluxes and compared them with the experimental labeling information until an optimal fit was reached [135]. The used network comprised 75 stoichiometric balance equations for pathways of central carbon metabolism including fluxes into biomass formation and metabolite export (Supplement Table 2). After flux parameter estimation, confidence intervals were determined in 50 iterations by a Monte-Carlo sensitivity analysis. For flux visualization the open source tool VANTED [136] including the FluxMap add-on [137] was used.

##### 4.16.1 Visualization of multi-omics data sets and pathway mapping.

The primary pathways for central carbon metabolism were manually created and annotated using xml editor of the open source software Inkscape (<http://inkscape.org/>). The primary pathway maps were then used to map the data (to visualize) obtained from the multi-omics experiments with a free web based application ProMeTra [7].

## 5. RESULTS

### 5.1 TRYPSIN DIGESTION OPTIMIZATION FOR THE SAMPLES OBTAINED FROM SPORULATING *B. SUBTILIS*

For precise controlled and reproducible growth behavior of bacteria it is often preferred to cultivate bacteria in well-defined fermenter or chemostat based cultivations. During controlled growth at low growth rates a sub-population of *B. subtilis* tends to sporulate – a process known as bet-hedging [138]. The ability of the *B. subtilis* to exhibit population heterogeneity poses a technical challenge when the protein lysates of these cells were subjected to trypsin digestion in-solution for current bottom-up proteomics approaches. In the past, Kuwana et al. [139] were able to identify 165 proteins in a bottom-up proteomics approach from a single sample of *B. subtilis* spores after extensive prefractionation. In addition, the expression patterns of 26 selected proteins were characterized with LacZ reporter gene fusion assays. This approach required increased sample handling and several genetic constructs for the selected proteins. In an another study Wishwas *et al.* [140] identified 55 spore coat proteins via gel-free proteomics approach after isolating the insoluble spore coat fraction. Here, a potential pitfall for the gel-free proteomics approaches for characterizing spores was addressed and a simple method was established to overcome the problem and to reliably monitor the expression levels of several hundred proteins in sporulating *B. subtilis*.

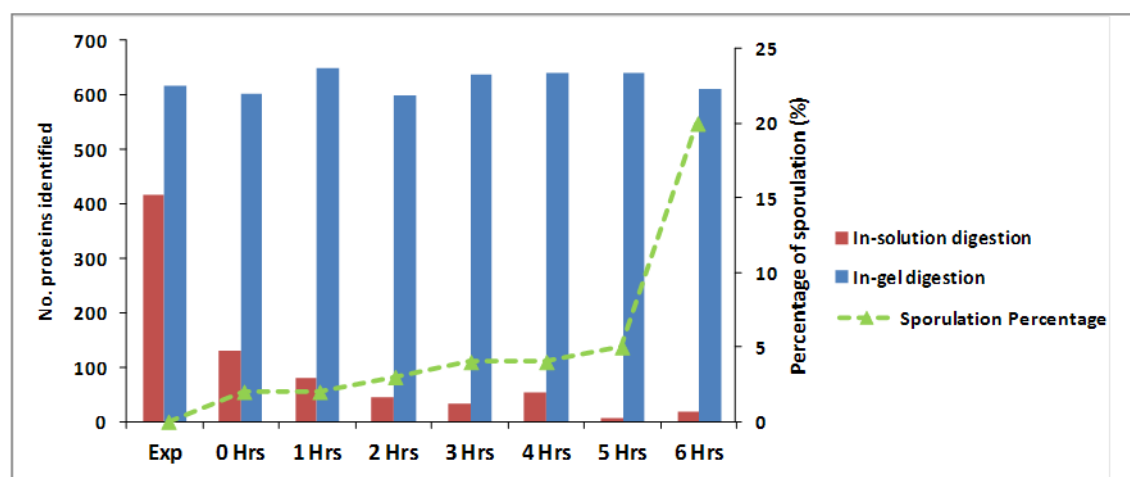

Figure 8: Effect of sporulation on protein identifications via in-solution digestion and in-gel digestion procedure. The *B. subtilis* strain 168 Trp<sup>+</sup> was grown in DSM media and the samples for protein preparation were harvested in exponential phase (Exp), early stationary phase (0 Hrs) and followed by sampling for every hour (see section 4.5.1). Percentage of heat resistant endospores was calculated by heat kill assay (see section 4.5.2). Percentage of heat resistant endospore (▲) of *B. subtilis* grown in DSM and number of proteins identified by LC-MS/MS by in-solution (■) and in-gel (■) digestion methods.

A shotgun proteomics strategy involves digesting proteins into peptides using an endoprotease (preferably trypsin) either in a solution (in-solution) or in a gel (in-gel). The first strategy (in-solution digestion) is much preferred over the second (in-gel digestion) due to its ease of handling and the benefit of handling smaller sample numbers [141]. However, we observed that samples that exhibit even partial sporulation, when subjected to in-solution digestion, yielded a significantly lower number of identified proteins compared to non-sporulating cells rendering the data unusable (Figure 8). The reason behind the low number of identifications was an increase of innate non-

Figure 9: Identification of non-specific proteolytic activity in proteins samples obtained from sporulating *B. subtilis* (A) SDS-PAGE: Lane1 – 15µg of fresh protein lysate of the sample 6 Hrs into stationary phase cultivated in DSM media, Lane2 – protein lysate incubated over night, Lane3 – protein lysate incubated overnight along with protein inhibitor cocktail, Lane4 – protein lysate with trypsin incubated overnight. (B) Number of proteins identified from each regulon via in-solution (■) and in-gel (■) digestion methods. (C) Quantification of proteins identified via in-gel digestion method - mean expression of the proteins regulated by the regulators over the time course. All time points were normalized to the exponential (Exp) condition. (▲) SigF (11 proteins), (△) SigE (56 proteins), (■) SigG (11 proteins), (□) SigK (25 proteins), (●) SigD (25 proteins), (○) Stringent response (85 proteins)

specific protease activity when *B. subtilis* started to sporulate. This is a common problem encountered in proteomic studies when *B. subtilis* is grown in chemostats at a very low growth rate, where partial sporulation is unavoidable.

To test our hypothesis *B. subtilis* was grown in Difco Sporulation Medium (DSM) [142] and samples for protein isolation were harvested every hour after the cells had entered stationary phase. The percentage of spores was determined using a heat killing assay. The sample with the highest percentage of spores (at 6 hrs) was used for the subsequent analysis. Overnight incubation (16-18 hours) of the protein lysate with or without trypsin had shown a similar pattern (Figure 9A) in a denaturing SDS-PAGE, where both lanes (lanes 2 & 4) were almost clear; indicating a strong innate non-specific proteolysis. Hence, adding a specific protease like trypsin into the samples that already had non-specific protease activity yielded non-tryptic peptides. This was evident in the subsequent LC-MS/MS analysis, which yielded substantially lower numbers of protein identifications (Figure 8). This innate protease activity was partially inhibited by adding broad spectrum protease inhibitor cocktail (Roche Applied Science) (Figure 9A Lane3); however usage of the protease inhibitors also inhibits trypsin activity.

An alternative approach to avoid non-specific protease activity is to fix/denature the proteins in a SDS-PAGE gel and then digest the gel trapped proteins. It has been reported in the past that separation of proteins by SDS-PAGE is mainly used for pre-fractionation and removal of any contaminants (detergents and other impurities etc.). Conventional in-gel digestion involves running a gel for 10 cm and then cutting the whole lane into a minimum of 10-15 bands and analysing them individually via LC-MS/MS in combination with MudPit [143, 144]. In order to keep sample numbers to a minimum and minimize technical variance we limited the gel run to 1 cm and sliced each lane into 2-3 bands. Each band was individually digested with trypsin and the resultant peptide solution was pooled and then desalted with C18 columns (Millipore, Bedford) and analysed via LC-MS/MS (Figure 6) (details in section 4.11.2).

This strategy improved the protein identifications of the regulon members (Figure 9B) and ensured consistent data quality across multiple samples in a time course (Figure 9C). As indicated in Figure 9C, groups of proteins involved in sporulation that are controlled by the sigma factors SigE, SigF, SigG and SigK [145] were up-regulated when the cells started to sporulate. SigK is the last sigma

factor activated during endospore formation that is responsible for the production of the late sporulation proteins [146], in the current study proteins controlled by SigK were up-regulated at later stage of sporulation as expected. On the other hand proteins controlled by SigD responsible for chemotaxis and several of the ribosomal proteins subject to negative regulation by the stringent response [28] were down regulated as expected for cells entering the stationary phase and initiating sporulation. This implies that the above described method can be reliably used for label free proteomics analysis and permits relative expression profiling of hundreds of proteins in sporulating *B. subtilis* (as shown in the Figure 8).

In conclusion the above proposed method simultaneously solves the problem of the non-specific protease activity encountered in sporulating *B. subtilis* and ensures high data quality for relative quantification via shotgun proteomics approach. This method was used in the subsequent sample processing for all the samples obtained from chemostats.

---

## 5.2 MULTI-OMICS PROFILING OF *B. SUBTILIS* DURING THE TRANSITION FROM GROWING TO NON-GROWING STATE

---

---

### 5.2.1 Transcriptome profiling of *B. subtilis* in tri-phase fed-batch fermentation

---

*B. subtilis* often encounters conditions of energy limitation depending on the availability of glucose and other carbohydrates in its environment. As glucose is the preferred carbon source, it is important to understand the global physiological adaptation to changes in environmental glucose concentration. Earlier studies had reported global transcriptome [147, 148] and proteome analyses [1, 50, 108] of glucose limitation and glucose starvation experiments performed in shake flask. However, none of the previous studies addressed the dynamic changes of *B. subtilis* physiology in response to the transition from growing to non-growing state in high cell density fermentation under precisely controlled conditions. Therefore, in the current study *B. subtilis* was investigated in a fermenter where the transition from growing to non-growing state (glucose limitation and/or starvation) of *B. subtilis* could be precisely adjusted and monitored.

The *sigK* mutant strain BSG112 was used in this study, which is unable to form mature endospores in order to avoid handling of spores with the 30 L fermenter used in this experiment. The sporulation sigma factor SigK, the last sigma factor activated during endospore formation, is responsible for the production of the late sporulation proteins [146]. So, deletion of *sigK* gene is not supposed to influence the early sporulation response and other adaptational changes associated with the transition of *B. subtilis* from growing to glucose limitation or starvation conditions. To understand the physiological adaptation of *B. subtilis* growing under different glucose concentrations, a three-phase fed-batch fermentation was performed (Figure 10). Briefly, *B. subtilis* was grown exponentially until the glucose was utilized to sub-optimal level and the glucose feed was maintained at low levels for 8 hours, this phase represents the glucose limitation phase. After 8 hours of glucose limitation, the glucose feed was stopped exposing *B. subtilis* to glucose starvation. A drop in the OD<sub>600</sub> was observed in this phase as the cells started to lyse due to glucose starvation. Samples for transcriptome analysis (Figure 10 blue dots) were harvested and microarray analyses were performed to elucidate the global physiological adaptation at the transcriptional level.

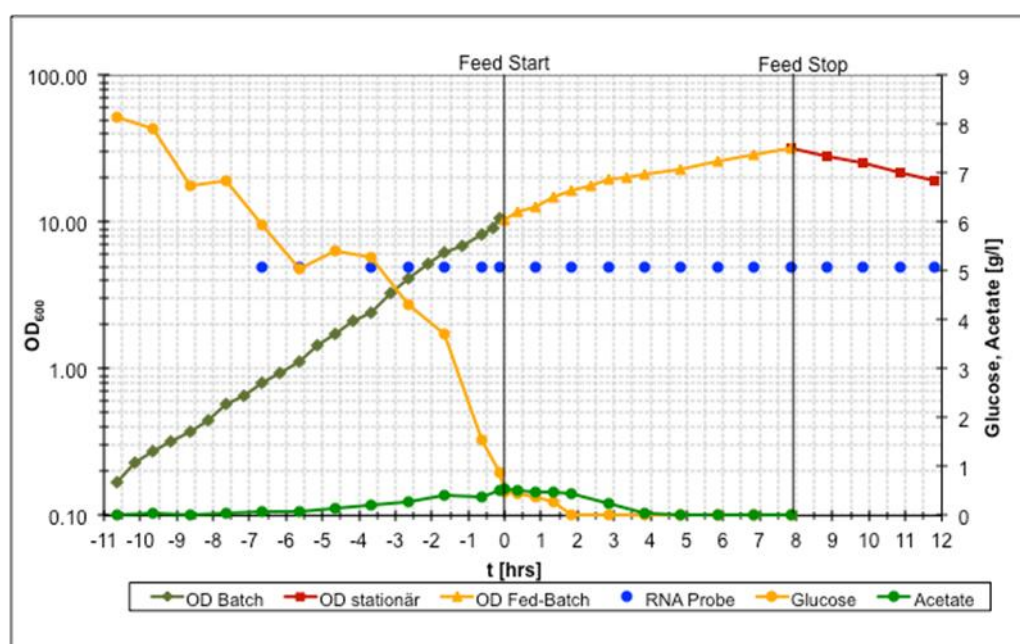

Figure 10: Tri-phase fed-batch fermentation of the *B. subtilis* strain BSG112 (*sigK* mutant) in M9 media (see section 4.3). The figure depicts the growth curve of the fermentation at OD<sub>600</sub>, glucose concentration (yellow lines) and sampling time points for transcriptome analysis were indicated as blue dots. Glucose feed was started at 0 hrs marking the start of glucose limitation phase and the glucose feed was stopped at 8 hrs marking the start of glucose starvation phase. (Cultivation performed by Dr. Beate Knoke, IBVT Stuttgart).

For the transcriptome data analysis, relative gene expression values obtained from the normalized ratio data were imported into Genedata Analyst for subsequent analysis. The activity of transcriptional regulators during exponential growth, glucose limitation and starvation was analyzed by representing the mean expression of respective target genes throughout the time course of the experiment (genes used for this analysis and their transcriptional regulators are mentioned in the supplementary table S1). Genes involved in the response to glucose limitation and starvation that are controlled by CcpA and the genes regulated by the alternative sigma factors SigB, SigD, SigE, SigF and SigG were considered for the analysis. As depicted in Figure 11, glucose limitation resulted in the induction of genes negatively controlled by CcpA. This induction was much stronger upon entry into glucose starvation phase. The observed regulatory pattern of the genes negatively controlled by CcpA was expected in view of the role of CcpA in mediating carbon catabolite repression (CCR) in the presence of glucose. The major function of CCR is to repress genes necessary for alternate carbon source utilization in the presence of glucose. The general stress regulon SigB exhibited a gradual increase during glucose limitation and further increased upon glucose starvation. Prolonged glucose limitation (after three hours into glucose limitation) in the second phase of the fermentation lead *B. subtilis* to initiate sporulation as reflected by the induction

of the SigF, SigE and SigG regulons. As the cells started to initiate sporulation response even before the entry into glucose starvation phase and deletion of *sigK* gene rendered an artificial situation for *B. subtilis* during the transition from glucose limitation to glucose starvation phase. To avoid this, a different experiment was performed where the cells transition directly from growth to glucose starvation (see next section)

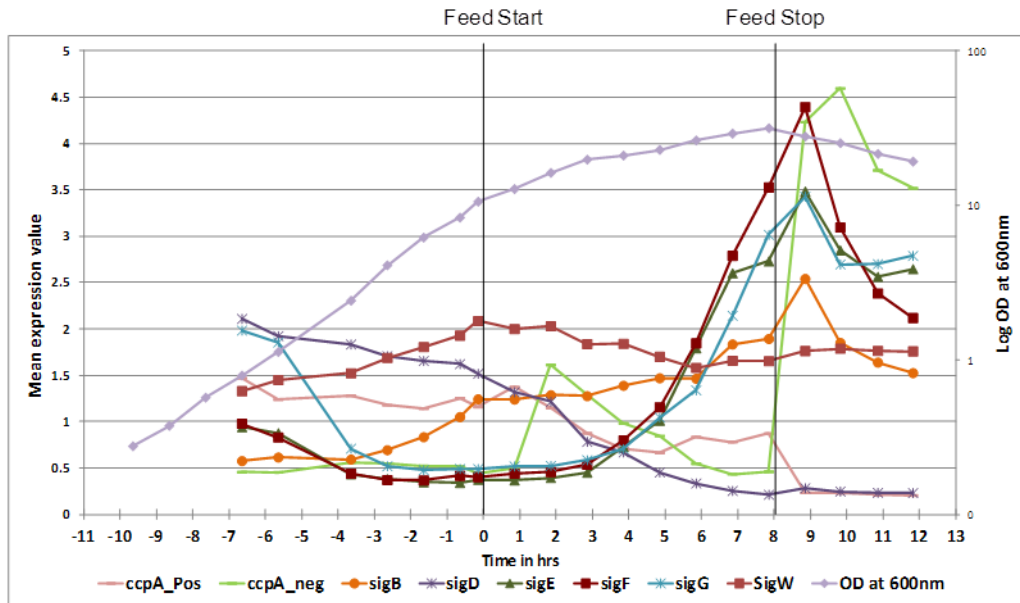

Figure 11 : Average (mean) expression profiles (y-axis) of the regulons controlled by the transcriptional regulators CcpA, SigB, SigD, SigE, SigF and SigG in a tri-phase fed-batch fermentation was represented above. Genes that belong to above mentioned regulons are mentioned in supplementary table 1.

## 5.2.2 Multi-omics analysis of *B. subtilis* in bi-phase batch fermentation

### 5.2.2.1 Transcriptome profiling

To prevent the interfering induction of sporulation response, which occurred during the prolonged glucose limitation in the tri-phase batch fermentation, *B. subtilis* was grown in a bi-phase batch fermenter. Within the first phase of this fermentation the cells were grown exponentially. After glucose was exhausted, the cells entered the glucose starvation phase. Samples were harvested for intra-and extra cellular metabolome analysis, intra-and extra cellular proteome analysis and transcriptome analysis. The sampling time points for all the omics analyses are marked as blue dots in Figure 12.

For the transcriptome data analysis, relative gene expression values obtained from the normalized ratio data were used for the subsequent analysis. To get an overview of the data, a Principal Component Analysis (PCA) of the transcriptome data was performed. This method involves a mathematical procedure that transforms a number of possibly correlated variables into a smaller number of uncorrelated variables called principal components (two components for two

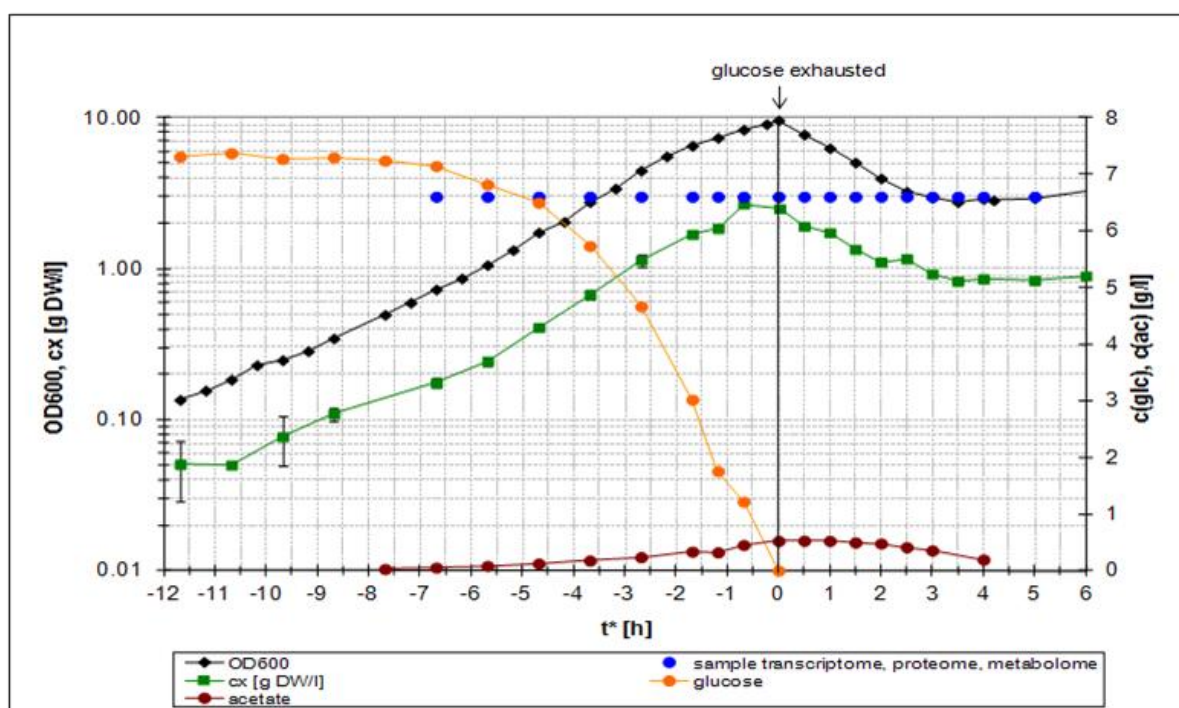

Figure 12: Bi-phase batch fermentation where cells transition from exponential growth phase to glucose starvation phase. The *B. subtilis* strain BSG112 (*sigK* mutant) was grown in M9 media (see section 4.3), growth curve at OD<sub>600</sub> (green line) was depicted in the figure. At time point "0 hrs" glucose was exhausted from the growth medium (yellow line). Blue circles denote the sampling for the transcriptome, proteome and metabolome analysis. (Cultivation performed by Dr. Beate Knoke, IBVT Stuttgart).

dimensional PCA and three components for three dimensional PCA). The first principal component accounts for the highest variability within the data, and each subsequent component accounts for remaining variability in a decreasing trend.

The ratio data for each of the time point against the common reference pool was considered for the PCA. In the PCA (Figure 13) the conditions segregated into two distinct groups, before (green) and after (red) glucose exhaustion. These two distinguished groups in PCA represent the extent of changes caused by the glucose exhaustion in the medium.

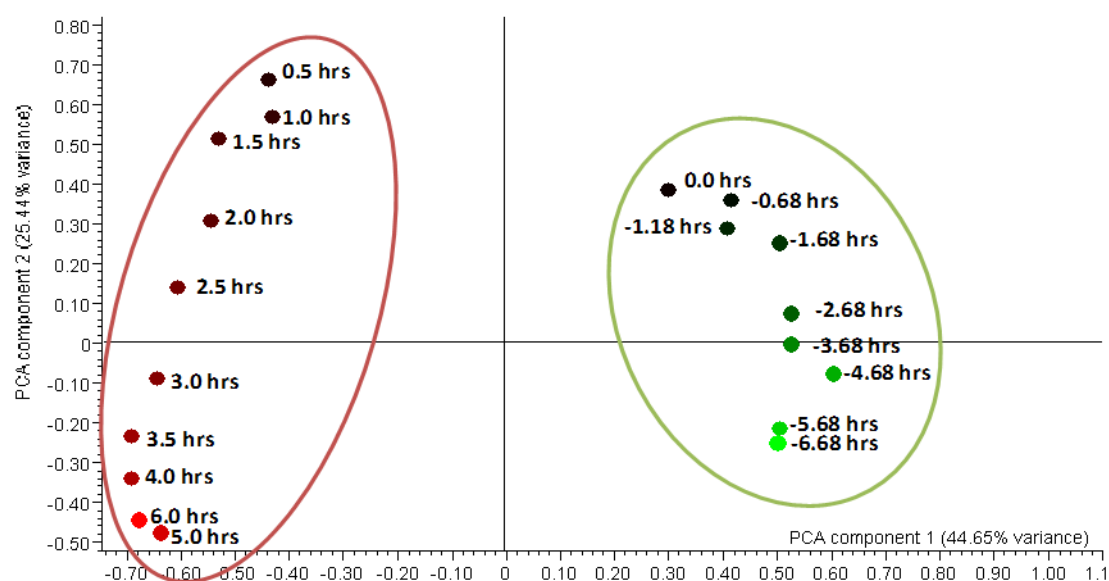

Figure 13: 2D-Principal component analysis derived from the transcriptome data of all the time points. A clear clustering was observed for all the samples from exponentially growing *B. subtilis* (green circle) and glucose starved *B. subtilis* (red circle).

Further comprehensive data analysis provided some insight into the temporal coordination of the sigma factors (Figure 14) in response to glucose starvation. Expression profiles from all the genes (regulon) that were controlled by their corresponding sigma factor or transcription factor were averaged and plotted along with the growth curve (Figure 14) (genes used for this analysis and their transcriptional regulators are mentioned in supplementary table S1). Genes regulated by CcpA showed a swift response to glucose exhaustion as anticipated. Most of the members of the SigB regulon containing 157 (SubtiWiki classification) genes were strongly up-regulated immediately upon glucose exhaustion. However, the up regulation of the SigB dependent general stress response was transient [4]. The SigW regulon was less responsive to glucose starvation compared to the SigB regulon. Reduced motility of *B. subtilis* under nutrient limiting conditions has been reported earlier

[1, 149]. In this study, the SigD regulon that is responsible for motility and chemotaxis was also down regulated upon glucose exhaustion.

In the course of prolonged glucose starvation, major sporulation regulons (controlled by SigE, SigF, and SigE) were highly induced. This analysis revealed that in response to glucose deprivation the general stress response and the sporulation response were temporally coordinated and separated. This coordination was achieved by the involvement of the corresponding sigma factors and various transcription factors for each of the process involved in the adaptational responses.

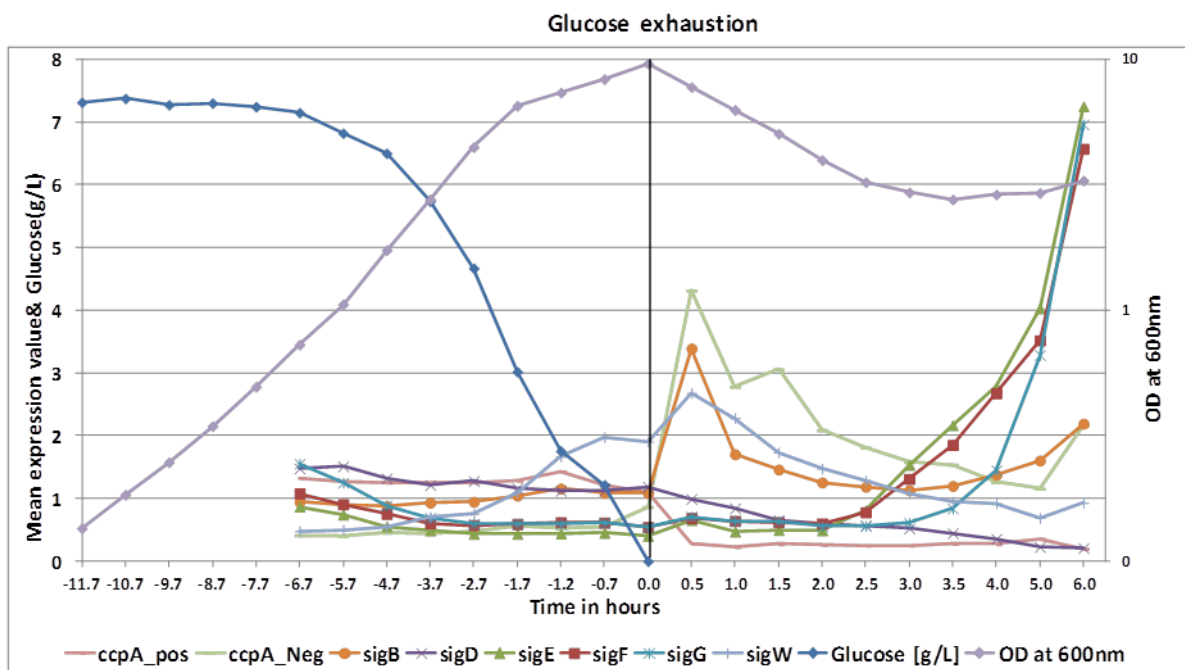

Figure 14: Average (mean) expression profiles of the regulons controlled by CcpA, SigB, SigD, SigE, SigF, SigG and SigW corresponding sigma factors was represented for the bi-phase batch fermentation. Genes that belong to above mentioned regulons are enclosed in the supplementary S1.

According to the SubtiWiki classification, there are 172 transcription factors that are responsible for controlling approximately 50% of the genes (2000 genes) in *B. subtilis*. Most of the regulators have at least two or more genes as their target, highest being 231 genes for the AbrB transcription factor. These transcription factors regulate their target gene expression by either repression or induction via various mechanisms. A detailed analysis of the regulons controlled by the various transcription factors had shown dynamic regulatory patterns. In Figure 15, the average expression profiles of significantly regulated regulons were depicted in two distinct clusters (A & B). Out of 172 regulons, 81 regulons were represented in the clusters (A and B) that were filtered after a statistical cut-off of three fold change and p-Value (ANOVA) of 0.01. Cluster A represents those regulons that were up-regulated at least in one of the time point when compared to the first time point. Cluster B

represents the regulons that were down regulated at least in one of the time point compared to that of the first time point. Two major kinds of regulatory patterns were observed in both clusters; first pattern: the majority of the regulons displayed a swift response to glucose concentration in the medium (e.g., stringent response, PurR, CcpA, LacR, CcpN etc.). The second regulatory pattern, instead of exhibiting a swift response to glucose exhaustion, is characterized by an initial induction (e.g., MdtR, FruR, GlpR) or repression (GerR, SpoVT, FrlR) before glucose exhaustion and later the regulons were gradually repressed or induced. This signifies the magnitudes of dynamic adaptation required by *B. subtilis* upon glucose exhaustion.

Cluster A contains several regulons that correlate with glucose concentration in the medium. Regulons that are related to sporulation like GerR, GerE, SpoVT were either not expressed or down regulated in the presence of glucose and were only up-regulated after prolonged glucose starvation. Nutritional stress stimulated the ribosomal associated protein (RelA) to synthesize (p)ppGpp and thereby modulate the transcription of several genes that mainly code for components of the translational apparatus, this is also known as stringent response [28, 29]. The genes that are controlled by ppGpp exhibited a sharp decline upon glucose exhaustion. A similar pattern was observed for the glucose uptake operon *ptsGHI* controlled by GlcT and the *gapA* operon that encodes the major glycolytic enzymes (GapA, Pck, TpiA, Pgm, Eno). The purine biosynthesis (PurR) and pyrimidine biosynthesis (PyrR) regulons were strongly down regulated as the cells cease to replicate in the absence of glucose.

Cluster B represents the majority of the genes that were up-regulated upon exhaustion of glucose. This group notably includes the regulons of the pleiotropic transcription factor CcpA (mediates carbon catabolite repression) and of CcpN, the repressor of the gluconeogenic enzymes PckA and GapB. Furthermore, several other regulons were induced upon glucose exhaustion that are responsible for secondary carbon source utilization such as LacR (lactose utilization), ManR (mannose utilization), TreR (trehalose utilization), GmuR (glucomannan utilization), AraR (arabinose utilization), LicT ( $\beta$ -glucan and  $\beta$ -glucoside utilization), LicR (lichenan utilization) and IolR (myo inositol catabolism). Regulons responsible for amino acid utilization and fatty acid degradation were also induced such as the HutP (histidine utilization), RocR (arginine utilization) and FadR (fatty acid degradation). Most of these changes in cluster B indicate the need for energy generation through various compounds in the absence of glucose.

Figure 15: Mean expression profiles of the genes controlled by their corresponding transcription factors. All the time points were normalized to the first time point (-6.68 hrs) and log transformed. Cluster (A) represents the regulons that were up-regulated in at least one of the time points, whereas cluster (B) represents those regulons that were downregulated in at least one time point. An effect size of three fold and p-value (ANOVA) of 0.01 was applied as a cut off. Regulon classification was obtained from SubtiWiki (Version 2012/1). \* Regulons with only one or two genes under their control.

### 5.2.2.2 Changes in the central carbon metabolism as revealed by multi-omics investigation

---

CCM specific protein abundance data were obtained by analyzing the samples via Multiple Reaction Monitoring (MRM) using QconCAT as an internal standard and measured on a triple quadrupole mass spectrometer (TSQ Vantage - Thermo Scientific). The ratio data against the internal standard (QconCAT) were obtained from the software Skyline and the ratio data was used to calculate the absolute concentration of the individual proteins. The absolute concentration data was used for the normalization with the control time point (time point -6.68 hrs). Transcriptome data for the pathways were obtained from the microarray analysis. The combined data were mapped on to the CCM pathway using the ProMeTra online software.

As glucose is the primary and preferred carbon source, it is valuable to understand the adaptation of the central carbon metabolism to changing glucose levels in a systems perspective. This involves generation and integration of multi-omics data, i.e., mRNA, protein and metabolite abundances. To this regard, the multilevel data was integrated on a custom drawn central carbon metabolism pathway map (Figure 16). Genes involved in the glycolysis showed a significant down regulation after glucose exhaustion; on the contrary genes involved in the TCA cycle were slightly up-regulated after glucose exhaustion. The strongest up regulation was observed with the gluconeogenic genes (*pckA* and *gapB*), whereas *fbp* which is not controlled by CcpN, the transcriptional repressor of gluconeogenesis, was unchanged. Furthermore, the majority of genes involved in the oxidative part of the HMP-shunt pathway (pentose phosphate pathway) were unchanged upon glucose exhaustion with the exception of 6-phosphogluconate dehydrogenase (*gntZ*) for the generation of ribulose-5-phosphate. The HMP shunt pathway plays an important role in generating NADPH for anabolic reactions and generating precursors for tryptophan and nucleotide biosynthesis; therefore the major genes involved in this pathway were not regulated upon the exhaustion of the glucose [148].

Figure 16 Time course visualization of multi-omics data of central carbon metabolism of bi-phase batch fermentation. To enable multi-omics comparison, data for all the time points were normalized to the first time point (-6.68 hrs) and log transformed. Capital bold letters denote the protein; italics fonts denote the mRNA expression profile and normal fonts represent the metabolites.

Almost for all the encoded proteins, the observed decrease in abundance levels were delayed which can be explained by the difference in the half-lives between mRNAs and proteins. Measurement of intracellular metabolite data was technically not possible for the time points of stationary phase due to increased cell lysis. Overflow metabolism that involves secretion of pyruvate into the extracellular medium was clearly observed as long as excess glucose was present and then the pyruvate was reutilized via TCA cycle to generate energy during stationary phase. Pathway level multi-omics visualization over the time course provided a unique perspective over the complex regulatory patterns involved with each molecule involved in the pathway during stationary phase.

Integration and visualization of multi-omics data sets is often a challenge especially in time course experiments due to the missing values of metabolites and proteins. Regarding the protein measurements, in a conventional shotgun mass spectrometric proteomics approach, it is common to have missing values across the time series due to the high dynamic range of the proteins in the crude protein lysate. In the current study, the missing values were minimized by implementing a targeted approach known as multiple reaction monitoring (MRM) which has the advantage of higher sensitivity and allows to perform the absolute quantification of the proteins. In a similar manner, with respect to the transcriptome data, the intensities obtained by the tiling array [116] hybridizations indicate a robust relative abundance of the mRNAs. In combination of both, relative intensities for mRNA and the absolute abundance of the protein, a correlation plot was generated () for the time point -4.68 hrs. Icd, GlnA and Mdh were the top three abundant in both protein and mRNA levels. The proteins which were involved in the proline biosynthesis and gluconeogenesis displayed lower mRNA and protein abundances. The regression coefficient for the correlation was 0.66 which was close to the value of 0.77 in *Escherichia coli* as measured by Taniguchi *et al.* (2010) [150]. Taniguchi *et al.* measured one protein at a time by fluorescence tagging and mRNA abundance from RNA sequencing (RNAseq). Given the fact that mRNA half-life and protein half-life are dramatically different; the correlation between their abundances was in a good fit. However for the stationary phase sample 5.0 hrs after glucose exhausted (Figure 17B) the correlation coefficient was 0.52 indicating a further mis-match between mRNA abundance and protein abundance.

### 5.3 WHOLE-TRANSCRIPTOME ANALYSIS OF *B. SUBTILIS* AT HIGH TEMPERATURE, LOW TEMPERATURE, HIGH SALT AND DURING GLUCOSE STARVATION

The *B. subtilis* wild type strain 168 Trp<sup>+</sup> was used to comprehensively compare the adaptation of transcription to stress conditions that are encountered by *B. subtilis* in its environmental niches at a global scale in a strand-specific manner to explore the transcriptional plasticity of *B. subtilis*. This comprehensive study was performed within the framework of two European projects BaSysBio and BaCell-SysMO and the stress conditions investigated in this dissertation include growth at high temperature (51°C), low temperature (16°C), high salinity (1.2M NaCl) and glucose starvation (exponential phase, early stationary/transient phase and stationary phase). For the growth at low temperature, high temperature and high salt, bacteria were cultivated in SMM medium. For the glucose starvation experiments M9 medium with glucose and malate were used as the carbon source. All these conditions were performed in shake flasks with three biological replicates for each condition. Transcriptome analysis was performed using the high resolution tiling array technology [93, 116]. The intensity data obtained from the tiling array were median normalized and ratio data were obtained by normalizing to the respective experimental control conditions.

Figure 18 : Principal component analysis of the transcriptome data obtained from the tiling array analysis. The *B. subtilis* wild type strain 168 Trp<sup>+</sup> was grown in SMM media at (A) high temperature (51°C), low temperature (16°C), high salinity (1.2M NaCl) and (B) glucose starvation in M9 media (exponential phase, early stationary/transient phase and stationary phase).

A three dimensional PCA analysis of the median normalized transcriptome data is depicted in Figure 18: The excellent biological and technical reproducibility of the experiments is visualized in the PCA as the samples from the same condition clustered closely together. The distance between the different clusters indicates the changes induced by the different growth conditions.

A bird's eye view comparison between the conditions is visualized in the Figure 19. Distribution of the expression profiles of the complete transcriptome data when compared to the respective controls are shown in Figure 19A. The scattering of the values around the median represents the magnitude of the adaptational response to the corresponding stress condition. Among the stress conditions that were investigated in this context, the M9 stationary phase sample representing glucose starvation had the highest distribution around the median. This indicates that glucose starvation was the most demanding stress condition for *B. subtilis* among the tested stress condition. This observation is also reflected in the number of genes that were regulated upon each stress condition (Figure 19B). Glucose starvation alone accounted for the regulation of more than 1000 genes followed by growth at 16°C, 51°C and continuous growth at high salt, respectively (supplementary table S2).

Figure 19: Magnitude of the changes associated with each of the stress conditions. A) Data distribution of the complete transcriptome for each of the conditions when compared to their respective controls (log<sub>2</sub> ratios). The wider the distribution of the expression profiles from the median, the greater is the dynamic physiological response of *B. subtilis* to that of the respective stress condition. B) Number of genes that were regulated in each condition when compared to their respective controls. A statistical cut-off of 3 fold change and p-value of 0.01 was used. Detailed information about the regulated genes was enclosed in supplementary table S2.

A detailed analysis of the genes involved in the functional categories obtained from SubtiWiki database is shown in Figure 20. Figure 20A shows the heat map of the averaged expression profiles of the various categories covered by the main category “Lifestyle”. This category represents almost all the major processes required by *B. subtilis* to cope up with environmental stress conditions. The following noticeable changes were observed within the functional categories. Chemotaxis was down regulated in all stress conditions, however, to a lesser extent during growth at high temperature. As expected heat shock proteins were up-regulated at high temperature. Genes of the functional category “Coping with hyper osmotic stress” were up-regulated in cells grown at only high salt as well as high temperature. Genetic competence was down regulated at both high temperature and low temperature growth. Another major response was the up regulation of the general stress response, controlled by SigB, in all the stress conditions, but to a lesser extent during continuous growth at high salt conditions. The largest category containing 348 genes is “sporulation proteins”, which was strongly induced during glucose starvation in M9 medium and to a lesser extent during growth at low temperature. The changes associated with sporulation genes partly account for the high biological variation induced by the glucose starvation compared to the remaining stress conditions in Figure 19.

Figure 20B shows the averaged expression profiles of the metabolic processes among the stress conditions. Glucose starvation could affect the highest number of metabolic pathways among the other tested stress condition. Most of the anabolic pathways were down regulated due to glucose starvation, whereas catabolic processes were up-regulated during glucose starvation. These anabolic processes include biosynthesis of cell wall, lipids, cofactors, amino acids etc. The catabolic processes include utilization of amino acids, specific carbon sources, lipids, nucleotides, nitrogen sources etc. As expected iron metabolism was up-regulated only during growth at high salinity [151]. To conclude, metabolic regulation was less pronounced for heat, cold and high salt stressed *B. subtilis* when compared to glucose starvation.

Figure 20 : Heat map overview of expression of the genes involved in metabolic and lifestyle categories. Fold change in comparison to their respective growth controls were obtained from the average expression profiles of the genes categorized by SubtiWiki functional classification A) Lifestyles and B) Metabolism. Number of genes representing each category is represented within the brackets.

#### 5.4 MULTI-OMICS STUDY OF OSMOSTRESSED- AND OSMOPROTECTED *B. SUBTILIS* UNDER GLUCOSE LIMITING CONDITIONS

In its environmental niche *B. subtilis* often encounters a combination of stress conditions. As a result of frequent drying out and scarcity of nutrients, *B. subtilis* might also experience a combination of high osmolar environment and energy starvation. *B. subtilis* has the ability to protect itself from high osmolar environment by either synthesizing proline or by importing osmoprotectants like glycine betaine when available in the environment [85]. However, to endure a combination of stress conditions requires well-orchestrated complex adaptational responses. To understand the intricate adaptational responses a multi-omics level investigation was performed.

Figure 21 : Experimental overview of the multi-omics investigation of the adaptation of *B. subtilis* to glucose limitation, simultaneous glucose limitation and osmoprotection. *B. subtilis* 168 Trp<sup>+</sup> was grown in chemostats under glucose limitation ( $\mu_{\max} = 0.1 \text{ h}^{-1}$ ), osmoprotection ( $\mu_{\max} = 0.1 \text{ h}^{-1} + 1.2 \text{ M NaCl}$ ) and osmoprotection ( $\mu_{\max} = 0.1 \text{ h}^{-1} + 1.2 \text{ M NaCl} + 1 \text{ mM glycine betaine}$ ). Samples for multi-omics analysis were harvested after the cells reached the metabolic steady state (see Figure 22A).

In this study, the adaptational responses of continuous growth at high salt and the effect of osmoprotection by providing external glycine betaine in combination with glucose starvation were investigated. For this cells were grown at high salt ( $\mu_{\max} = 0.1 + 1.2 \text{ M NaCl}$ ), at high salt in

the presence of glycine betaine ( $\mu_{\max} = 0.1 + 1.2 \text{ M NaCl} + 1 \text{ mM glycine betaine}$ ; osmo protection) and under glucose limitation as control condition ( $\mu_{\max} = 0.1$ ) (Figure 21). Glucose limiting condition devoid of additional stress was considered as control for salt-stress and osmoprotection. Three biological replicates for each condition were investigated and an additional culture with  $^{13}\text{C}$ -glucose (label) was used to investigate the flux through the CCM pathway. All the cultivations were performed in collaboration with Prof. Christoph Wittmann group in Braunschweig and I contributed to the study by performing the transcriptome and proteome analysis.

All cultures were grown in chemostats at a constant growth rate of  $0.1 \text{ h}^{-1}$  (Figure 22A). Samples for the multi-omics investigation were harvested after steady state was reached i.e. after five volume changes. Samples were harvested for transcriptome, intracellular proteome, intracellular metabolome, extracellular metabolome and fluxome analysis (Figure 21). Analyses of the proteome and transcriptome were part of this dissertation, thus they will be discussed in more detail.

For the transcriptome data analysis, relative gene expression values obtained from the normalized ratio data were used for the statistical analysis and functional categorization. For whole proteome analysis, after brief protein purification via SDS-PAGE (see section 5.1) in-gel trypsin digestion was performed and the resultant peptides were analyzed on a LTQvelos-

Figure 22 : A) Cultivation profile of four biological replicates of salt-stressed *B. subtilis* 168 Trp<sup>+</sup> grown at  $0.1 \text{ h}^{-1}$  in M9 minimal medium. Metabolic steady state was obtained after 35 hrs of cultivation and sampling for multi-omics analysis was done approximately after 85 hrs. B) Principal component analysis of combined data from proteome and transcriptome analysis of the samples  $\mu_{\max}=0.1 \text{ h}^{-1}$  (control – blue cluster),  $\mu_{\max}=0.1 \text{ h}^{-1}+1.2 \text{ M NaCl}$  (osmoprotection – red cluster),  $\mu_{\max}=0.1 \text{ h}^{-1}+1.2 \text{ M NaCl}+ 1 \text{ mM GB}$  (osmoprotection + GB – green cluster).

Orbitrap mass spectrometer (Thermo Scientific). The raw data were processed in the Rosetta Elucidator software and normalized intensities for each protein were imported into Genedata Analyst for further statistical and functional analysis.

A combined PCA analysis (Figure 22B) for transcriptome and proteome data indicated a close clustering of the conditions representing the high reproducibility between the biological replicates. The osmoprotected samples clustered independently to that of the salt-stressed and the control samples, indicating the physiological differences between all three conditions.

---

#### 5.4.1 Analysis of transcriptional changes

---

To understand the global changes in the transcriptome data compared to the reference condition ( $\mu_{\max}=0.1$ ), the whole transcriptome data was normalized to the reference condition. 1150 genes were significantly regulated in either the high salt grown samples (osmostress) or those grown in the presence of high salt and glycine betaine (osmoprotection) compared to the reference condition with fold change value greater than three and p-value below 0.01 (after Benjamini-Hochberg correction). The regulated genes across all three conditions were subjected to a K-means clustering to reveal six distinct clusters (Figure 23, left box, details enclosed in supplementary table S3). To find enriched functional categories within each of the clusters, a Fisher's exact test was performed comparing the proportion of genes associated with a given functional category in a cluster to the proportion of genes with the respective function within all genes (SubtiWiki classification, third level). This test provided the enrichment of the functional categories within each cluster and a  $-\log_{10}$  p-value indicating the extent of enrichment.

Figure 23 : K-means clustering and functional enrichment of transcriptome data. Graphs showing the average expression profile of each cluster with standard deviation (left) and enriched functional categories using the Fisher's exact test (right). All samples were normalized to the control condition ( $\mu=0.1$ ). The functional categories were adopted from "SubtiWiki". Number of genes in the enriched functional categories in the cluster (X) and the total genes in the parent category(Y) were represented as (X of Y). Detailed information about the regulated genes was enclosed in supplementary table S3.

Cluster 1 represented the genes that were induced by growth in high salt and even further up-regulated under conditions of osmoprotection. The most enriched genes in this cluster belong to the SigB dependent general stress response, iron metabolism (*yukNOP*, *feuABC*, *yuiI*) and metal ion homeostasis. Cluster 2 represented the strongly down regulated genes in both growth at high salt and osmoprotection. This cluster represented majorly sporulation proteins (members of SigE, SigF, SigG, SigK regulons). Cluster 3 had the smallest number of genes (54 genes) among all the clusters. The four genes that were included under the functional category of “coping with hyper-osmotic stress” represent the genes of the *opuC* operon. The OpuC transporter system has transporting abilities for various osmoprotectants like glycine betaine, choline or carnitine and is induced by a sudden salt stress, but not in response to continuous growth at high osmolarity [116]. The cluster 4 includes the genes that were strongly down regulated during the growth at high salt and slightly recovered during osmoprotection. The majority of the genes in this cluster encode for sporulation proteins and enzymes involved in the utilization of specific carbon sources and amino acids. Most of the genes enriched in the category belong to “ABC transporters” which were involved in utilization of specific carbon sources and amino acids.

Cluster 5 represented the genes that were strongly up-regulated during growth at high salt and down regulated under conditions of osmoprotection. This cluster contains the most relevant class with respect to the experimental condition, i.e., “coping with hyper osmotic stress” including the *proH* and *proJ* genes. The other genes that belong to this class were *opuAA*, *opuE*, *gbsA* and *gbsB*. This cluster also contains genes involved in cell wall degradation and lipid metabolism (*yqiIHK*, *slp*, *ysxA*, *yflE*, *lip*, *ywpB*, *tagC*, *psd*, *yocH*), osmoprotectant uptake (*opuA*, *opuE*). The last cluster 6 represented the genes that were strongly down regulated by growth at high salt and then fully restored during osmoprotection. The majority of genes in this cluster belong to the categories chemotaxis and motility. The genes involved in chemotaxis were strongly down regulated in the high salt adapted samples and this was completely restored during osmoprotection.

---

#### 5.4.2 Multi-omics investigation of the central carbon metabolism

---

Apart from the global stress responses involved in the adaptation to growth under high salt conditions, *B. subtilis* possesses a very specific response mechanism in hypertonic medium. This response includes an initial influx of potassium ions that is followed by biosynthesis of high amount of proline as an osmoprotectant. This high amount of proline is synthesized from glutamate which is replenished from the TCA cycle. Glucose is the primary substrate that drives glycolysis and TCA cycle; however, in the current study only limited glucose was available for *B. subtilis* to maintain homeostasis between cell proliferation and production of high proline amount as an osmoprotectant. Hence, it is crucial to understand the adaptational strategy deployed with in the central carbon metabolism to endure at high salinity with limited energy source.

CCM specific protein abundance data were obtained by analyzing the samples via Multiple Reaction Monitoring (MRM) using QconCAT proteins as an internal standard. Measurements were done on a triple quadrupole mass spectrometer (TSQ Vantage - Thermo Scientific). The ratio data against the internal standard (QconCAT) were obtained from the software Skyline and these ratio data were used to calculate the absolute concentration of the individual proteins. The absolute concentration data was used for the normalization with the respective control sample (in this case  $\mu=0.1$  reference sample). Transcriptome data for the genes involved in the CCM pathway was obtained from the microarray analysis. The combined data from different omics platforms were mapped on the CCM pathway using ProMeTra online software [7].

Figure 24 : Integrated view of relative transcript, protein and metabolite concentrations. Data from salt-stressed cells (in the presence of 1.2M NaCl) is compared to control ( $\mu_{\max}=0.1 \text{ h}^{-1}$ ) condition without salt. Log<sub>2</sub> ratios of absolute protein abundances from MRM analysis, relative mRNA abundances from microarray analysis from section 5.4.1 and relative abundance of the metabolites were mapped onto the pathway using the ProMeTra online software [7]. Gene expression is represented in italics, protein expression in bold and surrounded by dashed rectangles and metabolite level by rounded rectangles.

The integrated results of the multi-omics data are presented in Figure 24 for the growth at high salt compared to the non-stressed cells (reference). The data mapped onto the pathway diagram indicate a minor overall up regulation of glycolytic enzymes and TCA cycle enzymes until 2-oxoglutarate (2OG) at both transcriptional and translational level with some exceptions like CitZ and PdhB. The proteins Pgi, FbaA, Pgm, PdhC and PdhD showed the strongest expression

among the glycolytic proteins. The rest of TCA cycle was relatively unchanged after the OdhAB and PdhD complex. However, the branched pathway from 2-oxoglutarate to proline was significantly up-regulated to meet the demand of the osmotically induced proline biosynthesis. Namely the co-transcribed genes for *proH* and *proJ* were significantly up-regulated at high salt concentrations, thus increase in the proline biosynthesis could be observed as well. It is known that proline leaks into the medium and has to be re-imported via OpuE. Interestingly the transcription of the genes that were responsible for proline degradation *putC* and *putB* in conjunction with the transporters *putP* and *opuE* were strongly up-regulated. Genes for the osmoprotectant uptake systems *opuA*, *opuB* and *opuD* were also up-regulated; on the other hand the broad spectrum osmoprotectant transport system *opuC* was down regulated by at least two fold. Among the osmoprotectant uptake systems *opuE* exhibited the strongest up regulation. Even though no precursor for glycine betaine biosynthesis was supplied, the transcription of the glycine betaine biosynthetic genes *gbsA* and *gbsB* were strongly up-regulated. The mRNA of mechanosensitive channel *mscL* was also up-regulated to maintain the intracellular homeostasis amid the accumulation of several compounds. Several genes involved in the overflow metabolism were up-regulated that include lactate biosynthesis and export, acetoin biosynthesis and acetate biosynthesis.

Multi-omics data mapped onto the pathway diagram for the CCM pathway during osmoprotection compared to osmostress is represented in Figure 25. Osmoprotection was accomplished by the supplementation of 1 mM glycine betaine to the growth medium already containing 1.2 M NaCl. When compared to the osmostressed cells, little transcriptional regulation in the central carbon metabolism was observed during osmoprotection except for few genes. Genes involved in glucose transport system (*ptsS*, *ptsH*, *ptsI*) were significantly up-regulated during osmoprotection. Interestingly the genes involved in gluconeogenesis (*pckA* and *gapB*) were up-regulated. In contrast to the osmostress the genes involved in the utilization of acetoin (product of over flow metabolism): the operon *acoA*, *acoB*, *acoC* and *acoL* were significantly up-regulated. The genes that were involved in uptake of proline and other osmoprotectants were strongly down regulated in the presence of glycine betaine. During osmoprotection most of the changes were observed at proteins level.

Almost all the proteins investigated during osmoprotection were either unchanged or significantly up-regulated in comparison to the osmostressed cells; though in some cases the transcriptional regulation was in contradiction. To start with GapA, there was strong increase of GapA protein though the mRNA of *gapA* was unaltered. This observation was also noted for several other proteins notably for Pdk, Eno, Pyk, PdhA and PdhB in glycolysis. In the TCA cycle

CitZ, Icd, Mdh, YtsJ and PckA, which were known to interact [59] with each other, were significantly up-regulated during osmoprotection in comparison to osmostressed cells. Other complexes like succinyl-CoA synthase (SucC, SucD) and succinate dehydrogenase (SdhA, SdhB, SdhC) were up-regulated as well. The most striking observation was that ProJ and ProH levels which were known to rise upon salt stress did not dramatically decrease if glycine betaine was present (osmoprotection) compared to osmostressed cells grown in the presence of 1.2 M NaCl. Furthermore, levels of ProA increased during osmoprotection, while transcription of the encoding gene *proA* even decreased if cells grown in the presence of 1mM glycine beatine were compared to those grown in the presence of 1.2 M NaCl only. The rest of the proline biosynthetic enzymes were present at increased level if cells grown under conditions of osmoprotection with those exposed to 1.2 M NaCl only. As mentioned earlier, these observations for the proline biosynthetic enzymes at protein level were not reflected at the transcriptional level suggesting a strong role of glycine betaine at translational or post translational level.

The flux calculations from the  $^{13}\text{C}$ -labelled glucose cultures (experiments performed by M. Kohlstedt, Braunschweig) are represented in the Figure 26. During the reference condition ( $\mu_{\text{max}} = 0.1$ ), the flux of the metabolized glucose was distributed across pentose phosphate pathway and glycolysis (Figure 26A). The central skeleton (glycolysis and TCA cycle) of the central carbon metabolism conceded the majority of the flux in this condition. Due to the lack of overflow metabolism a large extent of the flux from glucose was diverted to TCA cycle. Figure 26 B represents the flux distribution during growth at high salt. Remarkably, the cells were able to maintain the overall fluxes through the central skeleton network compared to the reference condition; only differing at two points. The first change includes the increase in the production of over flow metabolites from pyruvate, which was also observed at the transcriptome level. The second major and crucial increase in flux was observed for the production of proline and glutamine. This increase in flux towards proline signifies the role of proline in osmoprotection.

In the presence of glycine betaine, the overall flux distribution throughout the energy generating flux backbone of pentose phosphate and TCA cycle was maintained (Figure 26 C). On the contrary, the flux through overflow metabolism and the proline biosynthesis significantly dropped compared to growth at high salt concentrations. Furthermore, there was an increase in the flux through amino acid biosynthesis from oxalo-acetate and the flux through malate to

pyruvate. The decrease in the flux towards proline biosynthesis signifies the impact of osmoprotection via glycine betaine.

Figure 26 : Relative changes in metabolic flux distribution. Note – width of the arrows signify the magnitude of the flux. A) Relative flux distribution under reference conditions normalized to glucose uptake rate, B) Absolute fluxes in salt-stressed cells compared to non-stressed cells, C) Absolute fluxes in glycine betaine-protected cells compared to salt-stressed (figure courtesy by Michael Kohlstedt, Braunschweig).

On first view, the obviously homeostatic flux state of many of the biochemical conversions in carbon core metabolism (Figure 26 B and C) seemed to be in contradiction to the strongly increased expression level of many proteins (Figure 24, Figure 25). To understand the underlying mechanisms, the impact of salt ions on protein activity was investigated for selected proteins by *in vitro* enzyme kinetics measurements, since *B. subtilis* growing at high salt exhibit an elevated intracellular potassium content of 600 mM [76] (Experiments performed by Michael Kohlstedt, Braunschweig). Two of the most relevant candidates, phosphoglucoisomerase and isocitrate dehydrogenase, were selected. Indeed, the presence of 600 mM  $K^+$  reduced the catalytic activity of the two enzymes by 56% and by 41% (Figure 27). It was interesting to note that proline itself, added in stress induced amounts, could not rescue the catalytic efficiency of the proteins. However, addition of 650 mM glycine betaine, reflecting the intracellular state at 1.2 M NaCl

and 1 mM glycine betaine in the medium could partially restore the original enzyme activity (Figure 27–yellow line). The ability to increase the protein amounts to compensate for lower catalytic activity due to increased salt concentration seems to be a fundamental strategy of *B. subtilis* to cope with the high osmolar conditions. The stabilizing and activating effect of glycine betaine on protein activity at high osmolarity might explain its efficient osmoprotection compared to proline.

Figure 27 : Influence of NaCl, proline and glycine betaine on specific enzyme activity of A) Phosphoglucosomerase Pgi and B) Isocitrate dehydrogenase Icd. Effector concentrations were chosen according to metabolomics data obtained in this study and literature data. (Experiments were performed by Michael Kohlstedt, Braunschweig)

Absolute protein abundances of the proline biosynthetic enzymes (pmol per gram dry weight) are depicted in Figure 28. ProB, ProA, ProI and ProG enzymes are required for anabolic proline biosynthesis, whereas the ProJ and ProH enzymes synthesize the high amounts of proline required during osmoprotection. In both pathways ProA is a common enzyme. We now observed that ProA was present at higher levels compared to the rest of the proline biosynthetic enzymes already during exponential growth with growth limiting amounts of glucose. During growth at high salt, ProJ and ProH levels were up-regulated approximately five and eight fold, respectively. On the other hand ProA levels were only marginally increased (less than 1.5 fold). Surprisingly, during osmoprotection, all proteins involved in proline biosynthesis showed higher abundances compared to the reference condition. Despite the observed changes at protein levels, such an effect of glycine betaine on the transcript level of proline biosynthetic genes could not be observed (Figure 25). All the proteins involved in the proline biosynthesis were present in higher abundance in the presence of glycine betaine during osmostress.

Figure 28 : Absolute amount of proteins involved in proline biosynthesis in the three different conditions  $\mu_{\max}=0.1 \text{ h}^{-1}$  (control), 1.2 M NaCl (osmoprotection), 1.2 M NaCl+ 1 mM GB (osmoprotection). Absolute protein concentrations (pico mole/gram dry weight of the sample) were obtained from the MRM analysis. The size of the circle represents the relative abundance of the protein within the pathway.

Though glycine betaine is metabolically inert in *B. subtilis* it was able to influence several other pathways (not related to osmoprotection). Hence, it is crucial to understand the role of glycine betaine during normal growth and during osmoprotection.

---

### 5.4.3 Effect of glycine betaine during exponential growth and osmoprotection

---

The osmoprotection elicited by glycine betaine was already known [85], however, the additional physiological effect of glycine betaine during normal growth and at high salinity was not investigated in detail. Supplementation of glycine betaine at high salinity did not restore the protein abundances of CCM to the reference level); conversely a non-specific increase in the protein abundance was observed. Therefore, to understand the effect exerted by glycine betaine, we investigated the influence of glycine betaine on the growth physiology during normal growth, high salinity and osmoprotection.

To understand the influence of glycine betaine (GB) over the cellular physiology, the wild type strain *B. subtilis* 168 TrpC<sup>+</sup> was grown in four different conditions (Figure 29).with high glucose (0.5 % glucose) shake flasks; hence, unlike the chemostat cultivations a constant growth rate could not be maintained. The conditions tested in the experimental setup include growth in SMM, SMM + 1 mM glycine betaine, SMM + 1.2 M NaCl and SMM + 1.2 M NaCl + 1 mM glycine betaine (Figure 29). The growth rate was significantly increased in the presence of glycine betaine either in case of SMM or in SMM + NaCl + GB. To further understand the physiological impact of glycine betaine, samples were harvested for protein preparation at OD<sub>600</sub> 1 (sample volume equivalent to 15 OD units). All the samples were processed via targeted MRM for the central carbon metabolic proteins and label free LC-MS/MS for whole proteome analysis.

CCM specific protein abundance data were obtained by analyzing the samples via MRM using QconCAT as an internal standard and measured on a triple quadrupole mass spectrometer. The ratio data against the internal standard (QconCAT) were obtained from the software Skyline and the ratio data was used to calculate the absolute concentration of the individual proteins. The absolute concentration data was used for the normalization with the respective control sample (SMM growth control). For whole proteome analysis, after brief protein purification via SDS-PAGE, in-gel trypsin digestion was performed and the resulting peptides were analyzed on a LTQ Velos-Orbitrap mass spectrometer. The raw data were processed in Elucidator software and the normalized intensities for each protein were imported to Genedata for further analysis.

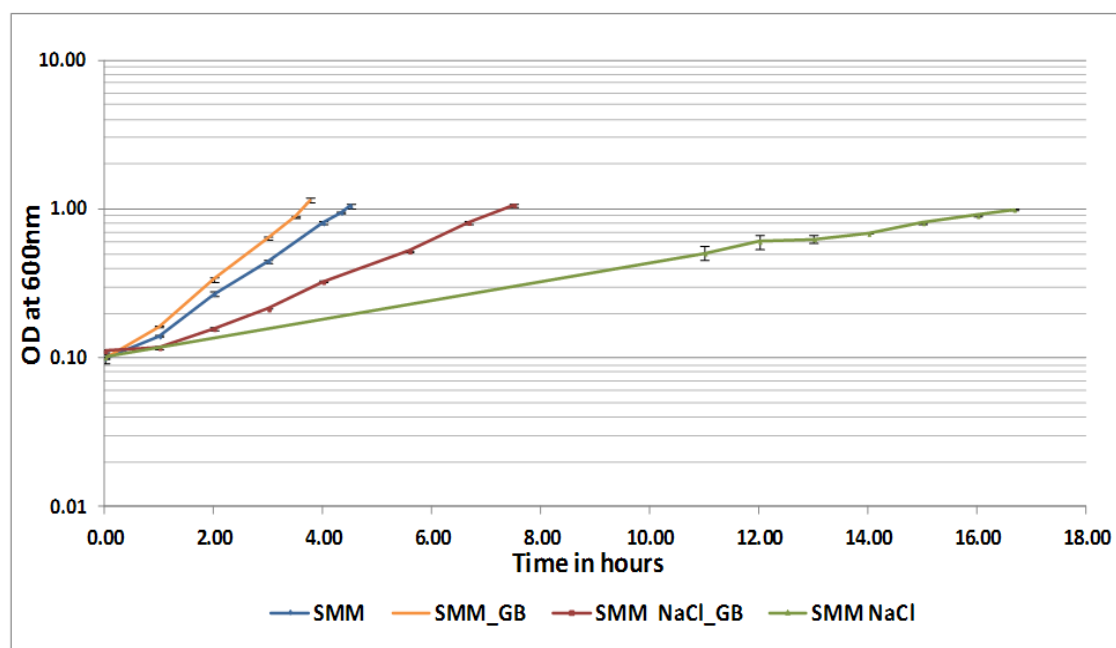

Figure 29 : Growth curve of the *B. subtilis* grown under different conditions. The *B. subtilis* wild type strain 168 Trp<sup>+</sup> was grown in SMM (control), SMM+1mM GB (GB control), SMM+1.2 M NaCl (osmoprotection), SMM+1.2 M NaCl+1mM GB (osmoprotection) as three biological replicates. Samples for the protein preparations were harvested at OD<sub>600</sub> 1.0 from all the cultivations.

Principal component analysis of the resulting data sets from the MRM and whole proteome analysis (Figure 30) revealed a separation based on the different conditions. Absolute amounts of the proteins that were targeted with the MRM approach listed in Figure 31 were taken into consideration for the PCA plot in Figure 30A. As a result of whole proteome LC-MS/MS analysis, 1089 proteins (with minimum of 2 peptides) were identified; a PCA plot of the whole proteome analysis is shown in Figure 30B. All the three biological replicates for all the four conditions clustered together for both data sets. The segregation of the clusters denotes the variation induced by the different cultivation conditions. It is evident from the PCA plots that the samples that received glycine betaine during normal growth differed significantly to the other samples.

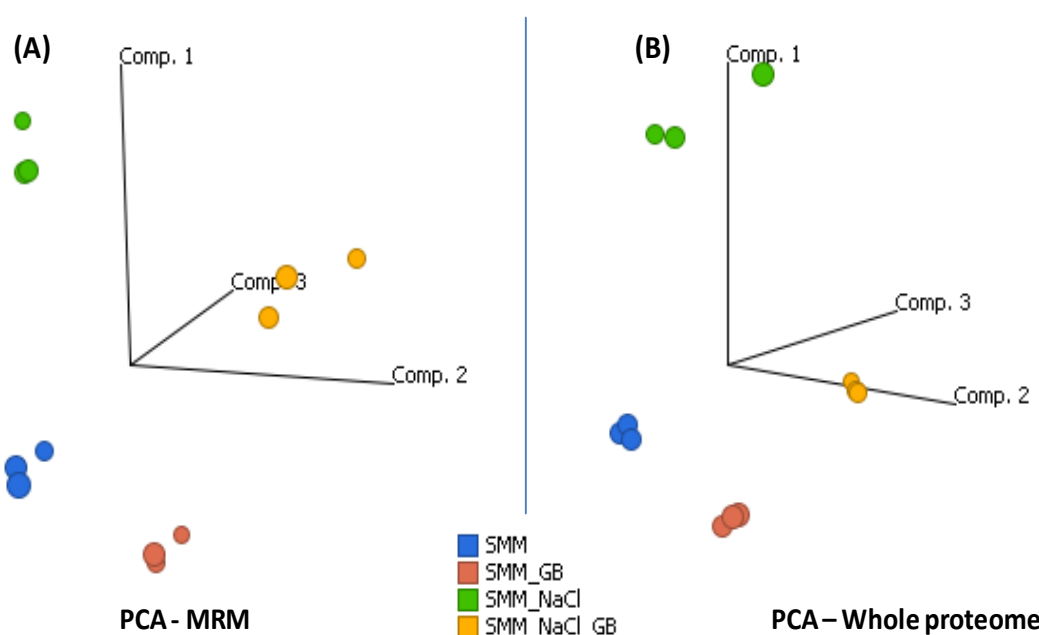

Figure 30 : PCA plots of the A) absolute protein abundances (data obtained from MRM analysis) of the proteins involved in the central carbon metabolism and proline biosynthesis and B) relative protein abundances of the all the identified proteins (data obtained from global proteome analysis). The *B. subtilis* wild type strain 168 Trp<sup>+</sup> was grown in SMM, SMM+1mM GB, SMM+1.2 M NaCl, SMM+1.2 M NaCl+1mM GB. The three biological replicates can be seen as three individual dots within the cluster.

Relative changes of the proteins involved in the central carbon metabolism for the above conditions are represented in the Figure 31. Ratio data was generated by normalizing all samples to the growth reference (SMM) and the ratio data visualization was performed. Subtle changes were observed in the core skeleton of the central carbon metabolism. GB alone did not alter the central carbon metabolism. However, high salt stress influenced levels of some key enzymes like Pgi and Icd, which both were slightly up-regulated. FbaA was also induced at high salt. PckA, which is a major gluconeogenic enzyme, was strongly induced during continuous growth at high salt even in the presence of high glucose concentrations. The glutamate synthase complex was strongly down regulated in the presence of high salt amid the requirement of high glutamate concentrations for the production of proline during osmoprotection. The key enzymes responsible for proline biosynthesis ProJ and ProH were strongly up-regulated. Furthermore, ProA was also slightly up-regulated (1.5 fold) during high salt growth. Interestingly, during osmoprotection (NaCl + GB) ProJ and ProH remained at high levels although the cells do not require proline as an osmoprotectant in the presence of glycine betaine. Apart from proline biosynthesis, FbaA, PdhC, PdhD, OdhA and OdhB were up-regulated upon osmoprotection.

Figure 31 : Relative changes of the proteins in the central carbon metabolism in all conditions compared to the reference condition (SMM). Log2 ratio of protein abundances were obtained from the MRM analysis of the samples cultivated in shake flask with SMM+ 1 mM GB (GB sample), SMM+1.2 M NaCl (NaCl sample), and SMM+1.2 M NaCl+1mM GB (NaCl+GB sample) compared to the growth reference SMM.

Global changes in the proteome as a result of various growth conditions are reported in Figure 32. Relative protein intensities were considered for the data analysis. After normalizing to the respective controls, an effective fold change of 1.5 and a p-value of 0.01 (after Benjamini-Hochberg correction) were applied to filter significantly regulated proteins. The resulting significantly regulated proteins were assigned to functional categories obtained from SubtiWiki. A Fisher's exact test was performed to elucidate the functional class enrichment.

117 proteins were significantly regulated by glycine betaine alone compared to the reference sample grown in SMM. 12 proteins of SigB regulon were down regulated in the presence of glycine betaine. Furthermore, proteins involved in the biosynthesis and acquisition of amino

acids and nucleotides were up-regulated in the presence of the glycine betaine. During continuous growth at high salt 336 proteins were significantly regulated. Of these 26 proteins belonging to the SigB regulon were up-regulated in the presence of high salt. 6 proteins involved in iron uptake and 9 proteins involved in the iron metabolism were up-regulated. This observation supports the earlier (section 5.3 and 5.4.1) transcriptome data analysis the *B. subtilis* grown at high salt experience severe iron limitation. Proteins that belong to translation, biosynthesis and acquisition of amino acids were down regulated during continuous growth at high salt, probably due to lower growth rate compared to the reference condition.

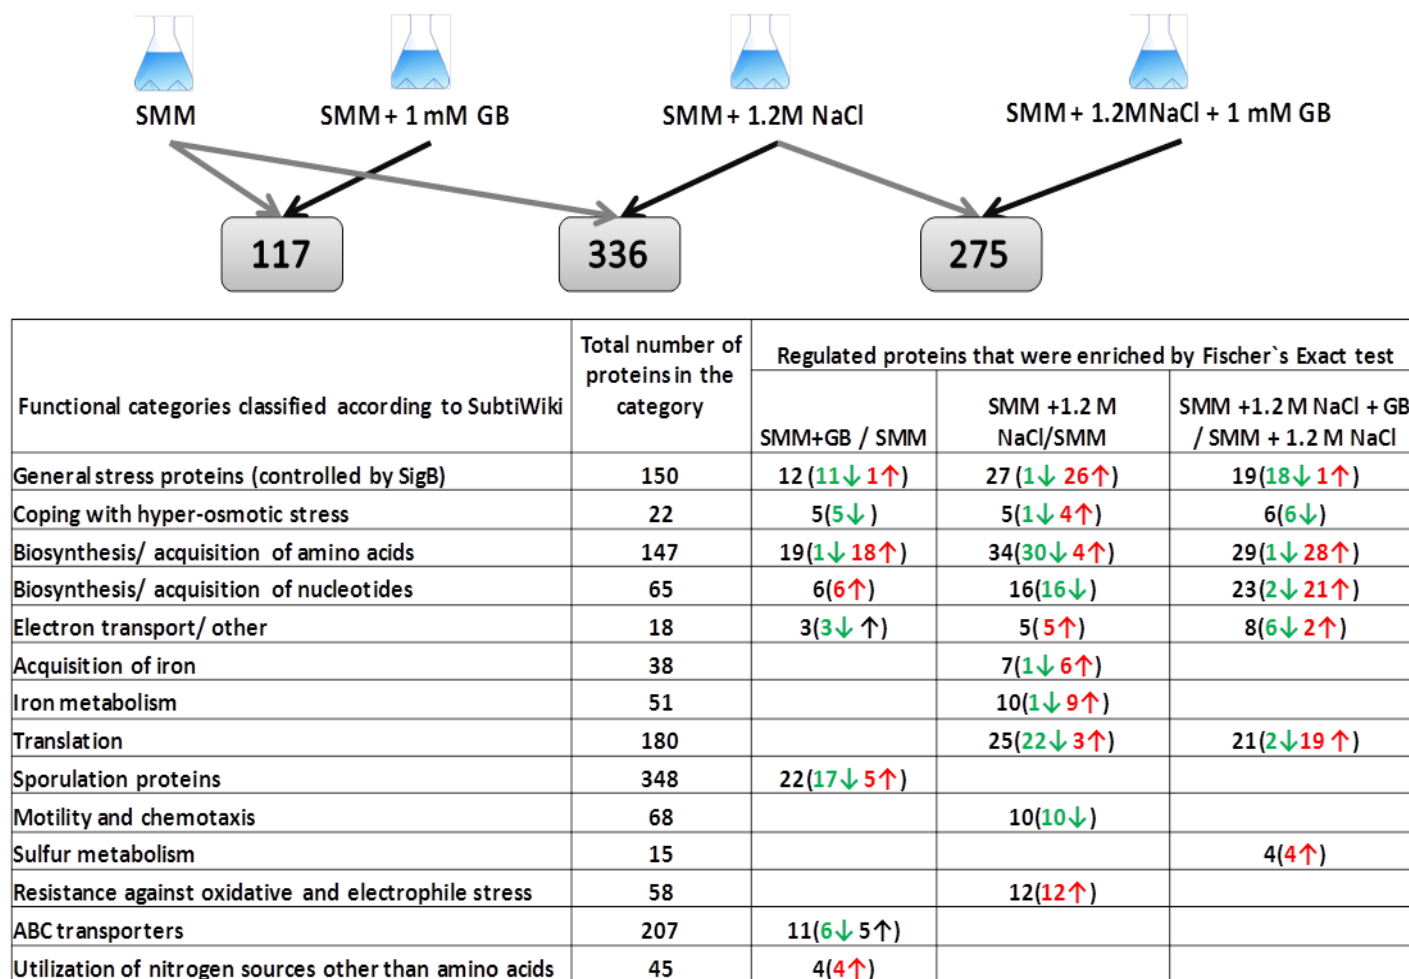

Figure 32 : Comparative analysis of influence of GB on global protein expression pattern. Number of proteins that were significantly regulated with a statistical cut-off of fold change 1.5 and p-value of 0.01 (after Benjamini Hochberg correction) between the conditions tested were represented in the above figure. Proteins that belong to the functional categories (SubtiWiki) for each set of the regulated proteins were shown in the brackets. The green numbers indicate the number of down regulated proteins and the red numbers indicate the number of up-regulated proteins.

Presence of glycine betaine during continuous growth at high salt provides better osmoprotection compared to the internally synthesized proline. This was phenotypically evident from the drastically improved growth rate during osmoprotection (NaCl + GB) and the changes observed in the proteome compared to continuous growth at high salt. The major changes observed in the proteome correlate with the increased growth rate with increased levels of proteins involved in the biosynthesis of amino acids, nucleotides and translation. Some of the proteomic changes observed in the presence of glycine betaine during osmoprotection (SMM+ NaCl + GB) could be also observed in the presence of glycine betaine during normal growth (SMM + GB) with a difference in the number of proteins regulated in each functional category. During osmoprotection the number of proteins regulated in each functional category was higher compared to the presence of glycine betaine during normal growth. This difference could be due to the fact that the influence of glycine betaine was higher or more effective when the cells were growing at high salt compared to the presence of glycine betaine during normal growth.

Figure 33 : Venn diagram representing proteins up-regulated in the presence of the glycine betaine in the reference condition and at high salt. Functional classes for the 30 proteins that were commonly influenced by GB are provided in the box.

The proteins that increase in level in the presence of glycine betaine either during normal growth or during osmoprotection are represented in the Venn diagram of Figure 33. 30 proteins were commonly up-regulated under both conditions. These proteins include those involved in the biosynthesis acquisition of amino acids, nucleotides and utilization of specific carbon sources. A group of 5 proteins (GudB, LysS, PurF, GSP13 (*yugL*), CarB) were previously described as unstable during glucose starvation in *B. subtilis* by Gerth *et al.* 2009 [1]. In this study Gerth *et al.* reported around 200 unstable proteins of which 80 proteins were targets of the ClpP/ClpC and ClpP/X proteases. Out of 200 of the unstable proteins, 45 proteins were covered in the current proteome study.

Levels of these unstable proteins under the different conditions analyzed in the current study are represented in Figure 34. All samples were normalized to the reference (SMM). For the osmoprotection sample the osmostress sample was taken as a reference to compensate for effects of high salt independent of glycine betaine. Log2 transformed ratios are visualized in Figure 34. This analysis indicates the increase in level of most of the previously known unstable proteins in the presence of glycine betaine either during growth or during osmoprotection. Furthermore, during osmostress there was a strong decrease in level/ apparently degradation of these proteins when compared to that of the other conditions. For several of those proteins that were decreased in level during osmostress the level was either restored or even further up-regulated during osmoprotection.

Figure 34 : Regulation of the unstable proteins [1, 2] in the presence of glycine betaine (SMM+ 1 mM GB), osmostress (SMM+1 M NaCl) and osmoprotection (SMM+1 M NaCl+10 mM GB) in comparison with their respective growth controls. Log2 ratios were derived by normalizing the relative protein quantities (from global proteome) compared to their respective controls.

**Table 2: Quantification of the impact of high salt and glycine betaine on presumably unstable proteins that were reported in Gerth *et al.* [1] and covered in the current study. (<sup>a</sup>)- Fold change was calculated for the GB and NaCl sample compared to the reference growth sample SMM, whereas fold change for NaCl+GB was compared to NaCl sample as a reference.**

The increase in level of these unstable proteins in the presence of glycine betaine could be due to two different reasons. The first reason could be that the level of these proteins could be regulated in a growth rate dependent manner. Since the growth rate was higher in the presence of glycine betaine the unstable proteins could have been maintained at higher abundance under this condition. The second reason could be a biophysical stabilization of the unstable proteins directly by glycine betaine. To conclude, in the presence of glycine betaine regardless of growth condition could indirectly affect many physiological processes by either improved growth rate or by biophysical protein stabilization.

---

#### 5.4.4 Comparative analysis of the central carbon metabolism during osmostress and osmoprotection at high and low glucose

---

During osmoprotection, *B. subtilis* requires additional resources to cope with growth at high salt concentrations. To investigate the adaptational responses towards osmostress and osmoprotection in the presence of high and low glucose a comparative analysis was performed. In Figure 35 a comparative analysis of the abundance of proteins involved in the CCM and proline biosynthesis was visualized. The ratio of the protein abundances for the high glucose condition (shake flask) compared to the low glucose condition (chemostat) was used for visualization. There was a significant effect of glucose concentration on the protein abundances within the CCM imposed by different glucose concentration. A major difference was observed for the glycolytic proteins; almost all of the glycolytic proteins were present at fivefold higher level in the shake flask samples compared to the chemostat samples. The proteins with the lowest difference in abundance within the glycolytic enzymes were the Pgi and PdhD. The pattern was different for proteins of the glycolysis and the TCA cycle. Many of the TCA cycle enzymes were present at lower level in the presence of high versus low glucose as expected. However, a few highly abundant proteins like Icd, FumC and Mdh displayed higher levels in the presence of excess glucose. Furthermore, the proline biosynthetic enzymes were present in lower amounts during high versus low glucose. Increased glycolysis in the presence of high glucose and decreased TCA cycle indicate an increase in over flow metabolism in the shake flask experimental setup due to the high glucose concentration.

Figure 35: Influence of glucose concentration during normal growth (none-stressed cells) and osmstress (1.2 M NaCl) onto the level of enzymes of the CCM and proline biosynthesis. Log2 ratio of protein abundances were obtained from the MRM analysis of high glucose samples cultivated in shake flasks (results from section 5.4.3) and low glucose samples cultivated in chemostat (results from section 5.4.2).

Comparisons of the effect of osmstress during high and low glucose on CCM and proline biosynthetic enzymes normalized to the respective non-stressed control are shown in Figure 36. This comparison was performed to analyze the adaptational differences of *B. subtilis* to osmstress in the presence of high glucose and low glucose. In the presence of high glucose, the central carbon metabolic enzymes were not significantly regulated when compared to its growth control (SMM). The only significant change was found for PckA which is a major gluconeogenic

enzyme and was strongly up-regulated in the presence of high glucose. Osmostress during low glucose significantly influenced the central carbon metabolism. Many proteins in the central core carbon metabolism were increased in level during osmostress compared to the none-stressed control cells; namely Pgi, FbaA, Pgm, PdhC, PdhD of glycolysis and CitB, OdhA, OdhB, FumC of TCA cycle were up-regulated. The switch point from 2-oxoglutarate to glutamate (glutamate synthase complex - GltA and GltB) was unchanged in the presence of low glucose but strongly down regulated in high glucose grown cells. Furthermore, the crucial proteins that are responsible for osmoprotection cells by producing high amounts of proline, ProJ and ProH, were induced to a similar extent regardless of the glucose concentration.

Figure 36: Comparative analysis of protein changes during salt stress (1.2 M NaCl) at high glucose (shake flask) and at low glucose (chemostat); both compared to their respective growth controls (none-stressed cells). Log2 ratio of protein abundances were obtained from the MRM analysis of shake flask samples (results from section 5.4.3) and chemostat samples (results from section 5.4.2).

A similar comparison for the osmoprotected samples with glycine betaine at high and low glucose was performed (Figure 37). Again, there was not much difference observed during osmoprotection at high glucose (left rectangle) in either central carbon metabolic enzymes or the proline biosynthetic enzymes. Major changes in protein level were observed during osmoprotection at low glucose (right rectangle). As seen in the osmoprotected samples grown in the chemostat (see section 5.4.2, Figure 25) most of the effects of glycine betaine were not represented at transcriptional level, so the effects of glycine betaine were probably post-transcriptional or translational. For some unknown reasons the stabilization effects imposed by glycine betaine were not significantly observed for the proteins involved in CCM unlike the unstable proteins at high glucose.

Figure 37: Comparative analysis of protein changes during osmoprotection (1.2 M NaCl + 1 mM GB) at high glucose (shake flask) and at low glucose concentrations (chemostat); both conditions are compared to their respective osmostressed samples (1.2 M NaCl). Log2 ratio of protein abundances were obtained from the MRM analysis of shake flask samples (results from section 5.4.3) and chemostat samples (results from section 5.4.2).

#### 5.4.5 Effect of ProH and ProJ over-expression and glutamate supplementation onto the osmo-adaptation of *B. subtilis*

Improving the osmoprotection capabilities of *B. subtilis* with its existing machinery would contribute to a better biotechnological application and might also provide new insights into the physiological regulation and its kinetics. To this regard, two questions were asked: 1) would higher levels of ProJ and ProH enzymes provide better osmoprotection? 2) would the supplementation with external glutamate omit a potential bottleneck and result in higher proline levels and hence a better osmoprotection?

In a different set of experiments we wanted to explore if the enzymes ProH and ProJ or glutamate levels constitute bottlenecks for the osmoadaptation of *B. subtilis*. These experiments were done in collaboration with the group of Prof. Erhard Bremer in Marburg and I contributed to this study with the proteome analyses described below. Three different strains were used in this experiment and each strain was grown in four different conditions in triplicate Figure 38. The conditions include growth in SMM (reference), SMM + NaCl, SMM + glutamate and SMM + glutamate + NaCl. The strains include JH642 (wild type), MDB22 (*amyE* control) and MDB28 (*proHJ* overexpression from the *amyE* locus). Overexpression of ProJ and ProH was achieved by replacing the original promoter by a perfect osmotically inducible SigA promoter (M10). The M10 promoter (Figure 39B) was a result of a series of mutations of its original promoter. The resultant promoter activity was assayed with TreA activity [152] and the results were shown in Figure 39C. All the mutant constructs were tested for the promoter activity during normal growth and the osmostress. Among the tested mutants, M10 was the strongest expressed

Figure 38 : Experimental setup and strain description for testing the effect of the *proHJ* over expression and supplement of glutamate during osmostress. The *B. subtilis* wild type strain (JH642), the *amyE* control strain (MDB22) and *proHJ* over expressing mutant (MDB28) were grown in four different conditions (SMM, SMM + 1.2 M NaCl, SMM + 10 mM glutamate and SMM +10 mM glutamate + 1.2 M NaCl). Strains construction and all cultivations were performed in the laboratory of Prof. Erhard Bremer in Marburg.

promoter which was a combination of three different mutations (M4, M5 and M7).

Figure 39 : Construction of the strain MDB28 for the overexpression of ProJ and ProH. A) Conventional SigA promoter. (B) Combination of several point mutations led to the final M10 (blue circle) mutant which was a combination of M6 and M7 mutations (C) TreA enzyme activity assays were performed for each of the tested mutant during normal growth and salt stress (0.4 M NaCl). The promoter with M10 mutation shows highest expression during normal growth and osmotic stress conditions (Experiments performed and data generated in the laboratory of Prof. Erhard Bremer in Marburg).

All samples mentioned above (Figure 38) were processed for MRM analysis of the central carbon metabolic enzymes and the proline biosynthetic enzymes. The results for the absolute protein abundance for ProJ and ProH proteins are shown in Figure 40. The amount of the proteins ProJ and ProH were at the same basal level in both wild type and *amyE* control strain. However, in strain MDB28 the basal level of non-stressed cells was strongly increased because of the M10 promoter mutation. During continuous growth at high salt, all strains exhibited an increase of ProJ and ProH compared to their basal levels. The uninduced levels of ProJ and ProH in MDB28 were equivalent to the induced levels of wild type and *amyE* control. Osmotically induced levels of ProJ and ProH in MDB28 were 5 - 6 fold higher compared to those of the control samples.

Figure 40 : Absolute protein concentration of the ProJ and ProH enzymes for wild type (JH642), *amyE* control (MDB22) and *proHJ* over expression mutant (MDB28) strains grown in SMM medium (control –in grey) and SMM + 1.2 M NaCl (salt stress –in black). Absolute concentration (fmol/ μg) of the proteins were obtained from MRM analysis.

A principal component analysis of the proteins of CCM and proline biosynthetic pathway of all the strains grown under various conditions is shown in Figure 41. The influence of both ProJ and ProH over expression and glutamate addition is represented in the PCA plot. A clustering of the samples corresponding rather to the cultivation conditions than the type of strain was observed. This dependency of the clustering on the cultivation conditions signifies the more prominent impact of the physiological variation rather than the strains genotype. Glutamate significantly affected the central carbon metabolism under both normal growth and osmotic stress.

Figure 41 : Principal component analysis based on the protein abundances involved in the central carbon metabolism and proline biosynthesis for the wild type strain (JH642), the *amyE* control strain (MDB22) and *proHJ* over expressing mutant (MDB28) grown in four different conditions (SMM, SMM + 1.2 M NaCl, SMM + 10 mM glutamate and SMM +10 mM glutamate + 1.2 M NaCl). Absolute protein concentrations obtained from MRM analysis was used for the PCA plot.

Absolute amounts of the complete set of proline metabolic enzymes under the tested conditions are comparatively shown in Figure 42. Apart from MDB28, in the normal growing cells, ProA was the protein with highest abundance among all the proline metabolic enzymes. This once again suggests that uninduced levels of the ProA are in excess to the other proline biosynthetic enzymes. During growth at high salinity, unlike ProJ and ProH, ProA was not significantly induced even though it was required for proline biosynthesis. This was also supported by the transcription data displayed in Figure 43 (from a different sample with similar experimental setup – data obtained from the section 3 of the results).

Figure 42 : Influence of ProHJ over expression and supplementation of glutamate on the level of the other proline biosynthetic enzymes during normal growth and salt stress. The strains used in the analysis were the JH642 (Wt- blue), MDB22 (*amyE* control -red) and MDB28 (*proHJ* overexpression - green). The concentration was reported in fmol/μg of protein extract. The standard deviation was calculated from the three biological replicates.

Though the *proA* gene was not osmotically regulated, its protein level increased during growth at high salinity in comparison to none-stressed control cells (Figure 42). Furthermore *proA* and *proB* are co-transcribed from a *sigA* promoter. But the protein of *proB* was down regulated during continuous growth at high salt in comparison to none-stressed control cells (Figure 42). This contrasting regulation of the proteins ProA and ProB translated from the same operon was also observed in the presence of glutamate only samples (SMM + 10 mM glutamate) and

osmostressed glutamate samples (SMM + 10 mM glutamate + 1.2 M NaCl). The transcriptional regulation of *proA* and *proB* under osmostress is represented in Figure 43. The contrasting regulation between transcription and translation might suggest an additional post-translational regulatory mechanism.

Regulation of mRNA during salt stress

Figure 43 : Gene expression regulation of *proA*, *proB*, *proJ* and *proH* genes during osmotic stress compared to the normal growth control (Log2 ratio of osmostressed vs control sample). The *B. subtilis* 168 Trp<sup>+</sup> was grown in SMM (control) and SMM with 1.2 M NaCl (salt stress). Data obtained from the tiling array analysis mentioned in the section 5.3.

---

#### 5.4.6 The effect of glutamate supplementation on osmoadaptation of *B. subtilis*

---

Glutamate is the precursor for proline that is required in high amounts for osmoprotection. Along with glutamate, osmoprotectants like proline and glycine betaine were supplemented to the cells growing in SMM in the presence of 1.2 M NaCl. These experiments were performed to compare the osmoprotective effects of the glutamate, aspartate, proline and glycine betaine. These experiments were done in collaboration with the group of Erhard Bremer in Marburg and I contributed to this study with the proteome analyses described below.

Dolezeal *et al.* 2006 had shown that addition of glutamate and proline to the osmostressed *B. subtilis* had shown similar growth improvement capabilities (data from doctoral dissertation of Monika Dolezal, Marburg/Lahn, 2006). As the supplementation of the medium with glutamate and proline had similar effect on growth, it is important to explore if the supplementation with glutamate could affect the expression of enzymes that are involved in synthesis of proline. In this regard, addition of glutamate did not affect the levels of ProJ and ProH proteins neither during normal growth nor during osmostress. However, marginal effects of glutamate addition onto the proteins involved in the anabolic proline biosynthetic like ProA, ProB and ProI were noted (Figure 44).

Inclusion of extra glutamate in the medium could also significantly influence several proteins of central carbon metabolism. Strong effects of glutamate were observed for FbaA, PykA, PdhB and PdhD in glycolysis, which were up-regulated in the presence of glutamate during both normal growth and osmostress (Figure 44). In TCA cycle Cit B and FumC was strongly down regulated by the addition of glutamate. On the contrary the main enzyme responsible for the utilization of malate the malic enzyme (YtsJ) was strongly up-regulated in the presence of glutamate indicating a probable increase in the pyruvate concentration. The other observation during osmostress without glutamate was that the gluconeogenic protein PckA was up-regulated. Upregulation of PckA during osmostress was also observed in earlier experiments in SMM media in the presence of high glucose (refer section 5.4.3, Figure 31). Hence, expression of PckA amid the presence of high glucose concentration under osmostress was reproducible again in this experiment. However upon the supplementation of additional glutamate during osmostress PckA was not up-regulated. A significant decrease in CitZ enzyme was observed in the presence of glutamate indicating a probable rerouting of pyruvate to overflow metabolism to produce more amount of lactate or acetate.

In summary, excess glutamate besides triggering partial improvement of osmoprotection also affected the levels of several proteins in the central carbon metabolism.

Figure 44 : Effect of supplementation of additional glutamate on proteins of central carbon metabolism during normal growth and osmostress. Samples for protein preparation for the MRM analysis were obtained from the *B. subtilis* wildtype strain JH642 grown in SMM (growth reference), SMM + 1.2 M NaCl (NaCl sample), SMM + 10 mM glutamate (glutamate sample) and SMM +10 mM glutamate + 1.2 M NaCl (NaCl+Glu sample). All samples were normalized to the growth reference (SMM) and Log 2 transformed. \*- data not significant for very low abundant proteins.

---

## 6. DISCUSSION

---

In its natural habitat, the soil, *B. subtilis* encounters several different stress and starvation conditions [4]. These stresses could be due to abrupt environmental changes or due to prolonged environmental stress conditions. The ability of bacteria to survive under these conditions is governed by extremely complex and sophisticated regulatory mechanisms that in turn respond to several of the environmental cues consisting of a wide range of internal and external signals. Sporulation is a long and energy consuming process that confers a state of dormancy to *B. subtilis* and is the last resort available for *B. subtilis* if all the survival strategies fail [145]. Therefore, understanding the adaptational mechanisms that enable survival of *B. subtilis* is of great importance for understanding its physiology.

The most common forms of stress conditions encountered by *B. subtilis* in its habitat are energy limitation, temperature fluctuation and osmotic stress. In this study, a similar set of environmental challenges was addressed in a laboratory setup. In the past, several studies [2, 80, 81, 119, 149] have extensively characterized each of those conditions with limited data coverage of the different cellular components mediating adaptational responses (e.g.: transcriptomics, proteomics, metabolomics). These omics data sets help to understand the regulation at different regulatory layers during adaptational responses to environmental conditions [153] and are a prerequisite for valid systems biology studies. In the present work, multi-omics and systems-wide approaches were used to understand complex adaptational responses.

### 6.1 MULTI-OMICS PROFILING OF *B. SUBTILIS* DURING THE TRANSITION FROM GROWING TO NON-GROWING STATE

---

*B. subtilis* was investigated in a chemically defined medium under glucose limited and glucose depleted conditions. A non-sporulating *B. subtilis* strain with a mutation in the gene *spoIVCB* encoding the sigma factor K that is responsible for the formation of mature endospores [154] was used. The non-sporulating strain had to be used in this experiment in order to avoid the necessity of removing mature endospores from the fermentation apparatus.

An initial experiment of a tri-phase fed-batch fermentation was performed to understand the genome-wide transcriptional responses to glucose limitation, followed by glucose depletion (see section 5.2.1, Figure 10). The mean expression profiles of the major regulons controlled by alternative sigma factors were not immediately up or down regulated upon glucose limitation (see Figure 11) indicating that glucose limitation alone is not sufficient to significantly perturb the system. Presence of glucose in the medium leads to carbon catabolite repression (CCR) by CcpA which is dependent on presence of the protein HPr and glycolytic intermediates G6P and FBP (see introduction) [35, 58, 155]. Binding of the CcpA-Hpr complex to the *cre* sites on the DNA involves repression of genes involved in metabolism of various secondary carbon sources. Under conditions of glucose limitation a derepression of genes responsible for secondary carbon metabolism was observed. However, the derepression of CcpA regulated genes during glucose limitation was not as strong (mean fold change of 3) as when the cells experienced glucose starvation (mean fold change of 9). This fine tuning of the CcpA regulation with varying glucose concentration is accomplished by a mechanism in which the glycolytic intermediates G6P and FBP increase the affinity of HPr-Ser46-P towards CcpA and thus enhance binding of the complex to *cre* sites [156].

The expression of the general stress response regulon controlled by SigB was gradually up-regulated upon glucose limitation. Energy stress (low ATP level) is sensed by RsbP (PP2C serine phosphatase) which is then conveyed to the RsbV regulator of SigB [157] (Figure 45). Low ATP levels likely limit the kinase activity of RsbW for RsbV thereby allowing SigB to be free [5]. During glucose limitation the extent of ATP depletion was obviously not sufficient to significantly increase SigB activity. But also during glucose starvation the expected strong expression of SigB regulon was not observed, which could be due to ongoing sporulation due to prolonged glucose limitation.

Figure 45: Regulation of the signal transduction pathway for the activation of SigB. Energy and environmental stress conditions affect SigB activity via the activation of the phosphatases RsbP and RsbU. The phosphatases then dephosphorylate RsbV, which leads to a partner switching of RsbW leaving SigB free to bind to the core RNA polymerase and thus transcribing SigB-dependent genes. [4, 5]. (Figure obtained from Hecker *et al.* 2007 [4])

Prolonged glucose limitation induced the sporulation response with the induction of the regulons SigE, SigF and SigG, consistent with the fact that both high cell density and energy starvation (glucose and amino acid limitation) are major stimuli for the initiation of sporulation [50, 145]. In the third phase of the fermentation upon entry into glucose starvation, the adaptational responses were overlapping and not separable from the ongoing sporulation response of the *sigK* mutant strain. Hence, a different experimental setup, a bi-phase batch fermentation was designed where the cells directly shifted from exponential growth to glucose starvation (section 5.2.2, Figure 12).

## 6.2 MULTI-OMICS ANALYSIS OF *B. SUBTILIS* CULTIVATED IN BI-PHASE BATCH FERMENTATION

In its habitat, while growing on various carbon sources, *B. subtilis* first utilizes the available glucose completely and if available malate is co-metabolized along with glucose [113]. While scavenging for alternative energy sources it concomitantly adapts to the starvation phase as long as possible and finally initiates sporulation. A previous study by Otto *et al.* (2010) [2] analyzed the transcriptome, metabolome and proteome of *B. subtilis* during exponential growth and stationary phase in shake flasks. Compared to the present study the samples were harvested at lower optical densities, due to growth in the shake flask, and the authors studied fewer (five) time points during the transition from exponential growth to stationary phase. A different study by Blom *et al.* 2011 was performed using a batch fermentation strategy, but rich medium (TY medium) to reflect regular laboratory conditions. The authors analyzed the transcriptome of *B. subtilis* in a time-resolved manner with 40 time points at 10 minutes intervals. The present study utilized a combination of chemically defined medium and high cell density batch fermentation with sampling time intervals of 30 to 60 min for a multi-omics characterization.

Unlike glucose limitation, the shift from exponential growth to strict glucose starvation was able to significantly influence the general stress regulon controlled by SigB and genes negatively controlled by CcpA. In the bi-phase fermentation both regulons showed a similar expression pattern but the SigB regulon was characterized by a more transient induction as expected. The main mechanism responsible for the transient response is the auto regulation of the *sigB* gene and the genes encoding the regulators RsbV, RsbW and RsbX, of which the anti-sigma factor RsbW exerts negative feedback regulation under most SigB activating conditions (Figure 46) [25].

Figure 46: Promoter organization of the genes involved in the regulation of SigB activity and auto regulation of the *sigB* gene. The genes for the protein that positively (*rsbV* and *sigB*) and negatively regulate (*rsbW* and *rsbX*) the SigB activity are under the control of SigB itself. (Figure obtained from Hecker *et al.* 2007 [4]).

Transcriptional plasticity during various stress conditions in *B. subtilis* is primarily due to the functioning of various alternate sigma factors [116]. The SigD regulon responsible for flagella synthesis and chemotaxis was significantly and gradually down regulated with the decline of glucose availability. The regulon of the extra cytoplasmic sigma factor SigW which is responsible for protection against antimicrobial compounds and cell wall stress [26] did not show a strong regulation when glucose was exhausted. However, in the study of Blom *et al.* (2011) [149] the SigW regulon was highly induced when cells entered late stationary phase in a nutrient rich medium. Availability of different types of nutrients between the two studies and other fermentation parameters might be responsible for this difference in the expression pattern of the SigW regulon.

As part of the adaptational response, glucose exhaustion led to significant changes in the major metabolic pathways both in the search of new energy sources and optimal use of existing resources. This was evident from the changes observed in the expression pattern for several regulons which contain genes for major metabolic pathways (see Figure 15) (81 out of 172 regulons were regulated more than threefold at least at one time point). A strong down regulation of biosynthetic pathways like purine biosynthesis (PurR regulon) and pyrimidine biosynthesis (PyrR regulon) was observed upon glucose starvation as the cells stopped to proliferate, hence, the need for nucleotides was diminished. This regulation is mediated by the purine repressor PurR. PurR represses its target genes upon binding to the Pur Box sequence of the target genes [158]. This binding is inhibited by the presence of PRPP (5-phosphoribosyl1-pyrophosphate) a product obtained from ribose-5-phosphate from HMP shunt pathway, which operates efficiently in the presence of glucose [159, 160]. On the other hand the PyrR regulates the genes involved in pyrimidine biosynthesis by binding to the anti-terminator region of the nascent mRNA in the operon and reducing the translation rate. This binding of PyrR is promoted by the presence of UMP/UDP/UTP [161, 162], which are in turn dependent on PRPP and ATP for their synthesis. Glucose starvation also led to amino acid starvation, which caused the stringent response via the ribosome associated protein RelA. RelA is also known to be involved in the activation of SigB during nutritional stress [163].

Glucose starved *B. subtilis* cells screen for the availability for new carbon source or other energy sources. This was apparent from the up regulation of several secondary carbon source-metabolizing genes during glucose starvation [50, 147]. This also includes amino acid and fatty

acid utilization genes in order to redirect the resources to pentose phosphate pathway via gluconeogenesis [148]. The pentose phosphate pathway provides the cell with NADPH and precursors for nucleotide biosynthesis in order to proliferate. All these pathways together play an instrumental role to regulate the cell proliferation before switching to sporulation response during famine.

Central carbon metabolism reacted swiftly to the glucose exhaustion as expected during glucose starvation. The upper part (glycolysis) and lower part (TCA cycle) of the central carbon metabolism showed two distinct patterns of regulation. Expression of the genes involved in the glycolysis was down regulated upon glucose exhaustion. This was partly achieved by the repressive effect of CggR on its own operon (*cggR-gapA-pgk-tpi-pgm-eno*), which hosts the major part of the glycolytic genes. CggR repression is antagonized in the presence of FBP, which is a product of glucose catabolism. On the other hand the TCA cycle was up-regulated after the glucose exhaustion. This is due to the two regulators CcpA (via carbon catabolite repression - CCR) and CcpC, which regulate *citZ*, *icd*, *mdh* and *citZ*, *citB* genes respectively. The activity of the regulators CcpA and CcpC is in turn dependent on the availability of the metabolites FBP and citrate which are the products of the glucose catabolism. Gluconeogenesis (*pckA* and *gapB*) was strongly up-regulated as soon as the glucose starvation began, as both genes are under control by CcpN, which actively senses the ATP and ADP levels. The dependency of these regulatory proteins (CcpA, CcpC, CcpN) on the intermediary metabolites is decisive for the regulation of the enzymes in the metabolic pathways. This is one of the main mechanisms that connect gene expression with environmental cues.

Overflow metabolism during excess glucose was observed in terms of pyruvate and acetate excretion into the medium and then re-utilizing both metabolites during the stationary phase. In the presence of excess glucose the depleted  $\text{NAD}^+$  pools can be regenerated by the synthesis of lactate as a part of overflow metabolism. However, the measurement of extracellular lactate was not possible with the methods used in this study.

When comparing the changes observed in the proteome with the changes of the transcriptome analysis, a sudden decline in the mRNA of the glycolytic enzymes was observed at transcriptional level, owing to short half-life of mRNA. Whereas these proteins were only

gradually down regulated as the half-life of proteins is much longer compared to mRNA; some proteins have lifetime even longer than the life cycle of the growing cells [164]. However, the gluconeogenic proteins (GapB and PckA) were immediately up-regulated after glucose exhaustion due to the fact that transcription and translation are coupled in prokaryotes, leading to an immediate increase in protein abundance following the spontaneous increase of the mRNA.

It was shown by Taniguchi *et al.* (2010) that correlation between mRNA abundance and protein abundance is often subjected to stochastic regulation [150]. The authors showed that at multicellular level the mean correlation (regression coefficient -  $r$ ) for the abundances of transcripts and proteins for several genes was  $r = 0.77$ . This correlation was obtained by using RNA-seq (for mRNA) and single molecule fluorescent microscopy (for protein) [6, 165]. Jong *et al.* (2012) showed in *B. subtilis* that at single cell level glucose starvation introduced large phenotypic heterogeneity across the culture leading to survival of only a sub population at the end. However, at single cell level in *E. coli* there was no correlation between the transcription and translation from the same gene [150]. This is due to the short half-life of mRNA and much longer half-life of the protein, as mRNA measurement only reflects recent (few minutes) history whereas protein measurement reflects history over a longer period of time. A similar correlation analysis between mRNA abundance and protein abundance was performed in the current study for the whole population. Relative mRNA abundances were obtained from the intensity values of tiling array experiments and compared to the absolute protein abundance obtained from the MRM analysis. The correlation  $r$  between mRNA abundance and protein abundance was 0.66 in an exponentially growing sample. The data obtained using the current methods reflect a mixture of cells and do not consider population heterogeneity effects as discussed above. However during the stationary phase the correlation coefficient of 0.52 was observed. In stationary phase it is expected that most of the mRNA associated to glycolysis are down regulated and the existing mRNA are immediately degraded, but in the case of proteins, though the translation is reduced, the existing proteins are not degraded immediately. Hence it is expected to have a mismatch between abundances of mRNA and proteins. On the contrary mRNA and proteins involved in TCA cycle start to increase in abundance in stationary phase, which shows an opposite regulatory pattern in comparison to glycolysis. Therefore the correlation coefficient as anticipated in stationary phase did not dramatically decrease in comparison to the exponentially growing cells. Absolute protein quantification calculated by MRM has a limitation; this method cannot be used to directly measure stochastic regulation. Nevertheless, a virtual stochastic simulation [166, 167] can be performed using the MRM data sets and microarray data sets to

understand the stochastic regulation. In a similar approach using MRM data Maeir *et al.* (2011) [166] had shown that in *M. pneumoniae* post-transcriptional regulatory mechanisms, in particular translation efficiency, rather than post-translational (protein turn-over) mechanisms predominantly contribute to protein abundances which are largely decoupled from overall mRNA abundances.

To conclude, an extensive time course investigation of high cell density fermentation was performed. The differences between prolonged glucose limitation and prolonged glucose starvation responses were investigated at transcriptome level. Central carbon metabolism pathway based multi-omics experiments were performed and the data were successfully integrated. A correlation analysis of relative transcript abundance and absolute protein abundance was performed. The correlation analysis gave an approximate estimate which was on par with much complex methodologies reported earlier.

---

### 6.3 WHOLE-TRANSCRIPTOME ANALYSIS OF *B. SUBTILIS* AT HIGH TEMPERATURE, LOW TEMPERATURE, HIGH SALT AND DURING GLUCOSE STARVATION

---

Analyses of the transcriptional changes associated with various stress conditions that are commonly encountered by *B. subtilis* help us to understand the adaptational responses necessary for its survival. In this study the main environmental stress conditions that are encountered by *B. subtilis* in its habitat were investigated: growth at high or low temperature, high osmolarity, and glucose limitation. Several studies in the past had reported transcriptional and proteomics changes associated with these stress conditions individually [2, 37, 50, 81, 93, 147, 148, 168]. In this thesis, as part of a structural re-annotation study of the transcriptome of *B. subtilis*, the transcriptome wide adaptational responses for the above mentioned stress conditions was investigated in detail with strand-specific tiling-arrays. The study, published by Nicolas *et al.* (2012) [116], was performed in two large consortia where the samples from the bi-phase batch fermentation (section 5.2.2) and the samples discussed here were part of 104 different conditions investigated. Altogether, 1583 new RNA features were reported and 2935 promoters were classified to the various sigma factors. These sigma factors accounted for 66 % of the variance in transcriptional activity. In the scope of the current thesis the physiological adaptation responses among the conditions mentioned above were analyzed.

Among the conditions tested in this study, glucose starvation influenced the largest number of genes. The magnitude of changes imposed are in the following decreasing order: 1) glucose starvation, 2) growth at 16°C, 3) growth at 51°C and 4) growth at 1.2 M NaCl. The physiological changes imposed by glucose starvation could be distinguished into two different categories: nutrient exploitation and the effects resulting from slow or no growth. In other stress conditions, the cells were analyzed during exponential growth in the presence of high glucose and varying growth rates due to the physiological stresses imposed.

Every different environmental stress demands a specific adaptational response from *B. subtilis*; this was evident from the distinct number of genes regulated and with minimal overlap of genes regulated in each of the stress conditions (Figure 47). Only 8 genes were commonly regulated among all four stress conditions tested.

Figure 47: Venn diagram representing the overlap of the significantly regulated genes during growth at high temperature (51°C) vs SMM, low temperature (16°C) vs SMM, high salinity (1.2M NaCl) vs SMM, glucose starvation (M9-stat) vs exponentially growing in M9 media (fold change cut-off of three, p-value 0.01 Welch t-test). List of the significantly regulated genes enclosed in supplementary table S2.

The genes involved in chemotaxis and motility were down regulated in all the stress conditions tested in this study suggesting that cells cease active swimming during prolonged stress conditions. Reduced expression of genes involved in chemotaxis was also reported earlier during sudden osmotic upshift (sudden osmotic shock) [81] and continuous growth at high salt (adaptation) [80] or growth at low temperature [118]. Of the proteins classified as heat shock proteins, the majority of which are molecular chaperones, the major heat shock proteins (GroEL, GroES, DnaK and GrpE controlled by the HrcA repressor), ClpC and HtpG were up-regulated more than two fold in cells grown at high temperature (51°C). These chaperones prevent proteins from misfolding and promote the refolding during growth at high temperature [169].

Sporulation was induced during glucose starvation [50] and growth at low temperature [118] making these stress conditions more demanding with respect to the number of genes required for adaptation than the heat and salt stresses. Sporulation-specific responses at low temperature involved the up regulation of genes that are associated to the SigF, SigE and SigG regulons [118, 170]. General stress response proteins controlled by SigB were up-regulated during starvation (as discussed earlier) [50, 171], at high temperature [70, 171], continuous growth at high salt [80, 171] and growth at low temperature [118]. Koburger *et al.* 2005 [147] had reported that SigB mediated general stress response as one of the major class of genes to be upregulated upon glucose starvation, the other major class being the genes under the control of stringent response which were down regulated upon glucose starvation. The SigB mediated stress response is also crucial for *B. subtilis* to survive in other conditions such as ethanol stress (9%), acid stress (pH

4.3) and desiccation as indicated by Völker *et al.* (1999) [171]. Other conditions that induce the SigB regulon include growth on plates, growth with glycerol as carbon source, biofilm formation, phosphate starvation, oxidative stress, and oxygen limitation [116, 172]. Several genes of the SigB regulon are also under the control of one or more other transcriptional regulators leading to an overlap between regulons within the transcriptional regulatory network. Nannapaneni *et al.* (2012) [172] performed a targeted microarray analysis examining 350 genes and defined the SigB regulon to contain 203 genes out of which 37 genes are also regulated by other regulators. Nannapaneni *et al.* have performed the study based on three previous [173-175] studies that described the SigB regulon. Based on the tiling array data, Nicolas *et al.* (2012) [116] classified 287 annotated genes and 133 previously un-annotated RNA features to be members of the SigB regulon. Of the 287 annotated genes, 214 were assigned to regulation by more than one sigma factor. This classification was performed based on the DNA sequences near the transcription start sites as well as the condition-dependent promoter activities as inferred from the expression levels downstream of the transcription start sites. Among the two latest studies that described the SigB regulon, the later study by Nicolas *et al.* is unbiased as the complete genome of *B. subtilis* was examined by microarray hybridizations, whereas the former study (Nannapaneni *et al.*) was based on annotated genes and in particular analyzed 350 genes previously reported to be controlled by SigB. To summarize, the ability of SigB to connect different regulons and indirectly co-ordinate various adaptational responses results in a higher order SigB modulon [4].

Major expression changes of genes involved in metabolism were observed in glucose starved *B. subtilis* cells. Glucose being the primary carbon and energy source for *B. subtilis*, glucose deprivation drives major alterations in the metabolic pathways. These changes include up regulation of the genes involved in exploring alternate energy sources and utilization of existing resources. The other metabolic responses correspond to growth rate effects where biosynthesis of various compounds was down regulated in glucose starved *B. subtilis*. The other stress conditions investigated in this study when compared to glucose starvation did not trigger the same magnitude of changes in genes associated to cellular metabolism. *B. subtilis* grown at high salt suffers from iron limitation thus inducing genes involved in iron metabolism [80, 151]. Several members of the Fur regulon which were associated to iron acquisition such as the genes involved in biosynthesis of the siderophore bacillibactin and other iron uptake systems were up-regulated [176]. As excess intracellular concentration of iron is deleterious to cellular physiology as it forms toxic hydroxyl radicals [177], iron homeostasis is achieved by the activity of the Fur repressor in the presence of excess iron and the release of the repressor causes the derepression

of the genes involved in iron acquisition and uptake during iron limitation [178]. Two previous studies analyzed the effect of high salinity on iron limitation in *B. subtilis* (Steil *et al.* 2003 [80] and Hoffmann *et al.* 2002 [151]) but used a different strain (JH642) [179] containing a mutation (*sfp*<sup>0</sup>) which prevents or strongly reduces the phosphopantetheinylation of DhbB and DhbF leading to highly reduced production of bacillibactin. The bacillibactin precursor 2,3-dihydroxybenzoate is a much less efficient iron scavenging compound, making this strain susceptible for iron limitation [176]. In the present study the *B. subtilis* strain 168 Trp<sup>+</sup> was used which is a Sfp<sup>+</sup> strain. However, even in the presence of a proper siderophore synthesis apparatus producing normal amounts of bacillibactin, a strong iron limitation could be observed under high salt conditions. Hoffmann *et al.* (2002) analyzed the DHB production in strains with *sfp*<sup>+</sup> (KE10) and *sfp*<sup>-</sup> (JH642) at 0.7 M NaCl; unlike JH642, in the KE10 strain DHB production was not increased during high salinity indicating no iron limitation in the cells containing *sfp*<sup>+</sup>. In contrast to the previous finding, in the present study using 1.2 M NaCl the genes of the *dhb* operon (Figure 48) were strongly up-regulated during continuous growth at high salt, indicating that the cells indeed experienced iron limitation at high salinity. This may indicate that at higher osmolarity - 1.2 M NaCl –in this study, compared to 0.7 M NaCl used in the previous study, even *B. subtilis* cells containing the *sfp*<sup>+</sup> gene experience iron limitation. Interestingly, in case of the halophilic bacterium *Chromohalobacter salexigens*, the requirement for iron is reduced at high salt, and the Fur regulator was shown to mediate iron homeostasis at high salinity [180]. Thus, the regulatory connection between iron homeostasis and high osmolarity might depend on the type of bacteria and their corresponding habitats, linked with distinct adaptational strategies to cope with changing osmotic conditions.

#### 6.4 MULTI-OMICS STUDY OF OSMOSTRESSED AND OSMOPROTECTED

Figure 48: Average Log<sub>2</sub> ratio (compared to the growth controls) of the expression of the *dhb* operon controlled by the iron sensing regulator Fur. The Log<sub>2</sub> ratios were obtained by comparing high temperature (51°C) vs SMM, low temperature (16°C) vs SMM, high salinity (1.2M NaCl) vs SMM, glucose starvation (M9-stat) vs exponentially growing in M9 media stress conditions. Data obtained from the tiling array analysis mentioned in the section 4.3.

---

### ***B. SUBTILIS* IN GLUCOSE LIMITING CONDITIONS**

---

In its natural environmental niche, *B. subtilis* often encounters multiple stress conditions that include nutrient starvation or limitation, temperature fluctuation, flooding or desiccation. In this study a combination of nutrient limitation and desiccation that are comparable to glucose limitation and growth at high salinity were simulated in chemostat cultivations. The usage of chemostats ensured a constant growth rate at any given condition by altering (via dilution) the concentration of the growth limiting factor (e.g. glucose) [181]. In addition to glucose limitation ( $\mu_{\max}=0.1$ ) and glucose limitation with 1.2 M NaCl, a third condition combining glucose limitation and osmoprotection (1.2 M NaCl + 1 mM glycine betaine) was investigated in a multi-omics approach. In the past, several studies had reported the flux data through central carbon metabolism (CCM) in *B. subtilis* cultivated in chemostat [182-185]. In the current study, for the first time, a multi-omics approach was implemented to analyze the molecules (mRNAs, proteins and metabolites) involved in the central carbon metabolism. As a part of the multi-omics analysis, a complete transcriptome analysis was also performed to understand the overall physiology under the tested conditions.

Several earlier studies addressed changes in gene expression associated with growth at high salinity in *B. subtilis* [80, 81, 151, 186], but had to cope with varying growth rates because the experiments had been performed using shake flask cultures. In the current study chemostat cultivations were performed at a unified growth rate, so the changes observed were arguably associated to the exclusive stress conditions imposed. This in combination with multi-omics investigation gave a comprehensive understanding of the adaptational responses in *B. subtilis*.

Major changes associated with growth at high salinity were discussed in the section 6.3; like induction of the genes in the general stress response (SigB regulon), induction of genes associated to iron metabolism, suppression of sporulation etc.. High osmotic strength in the medium prevented sporulation likely via multiple ways; e.g. by reduced expression and phosphorylation of Spo0A, reduced or no synthesis of SigE and SigF [187]. Changes in membrane composition (increased fluidity with saturated straight chain fatty acids) in hypertonic medium [133] that could inhibit KinA (two-component sensor kinase requires for sporulation initiation) leading to lowered Spo0A-P thereby impeding sporulation. Changes in phospholipid composition could also effect the correct folding of membrane proteins (e.g. SpoIIGA, FtsH, etc.) that process the pro-sigma factors (SigE and SigF) required for sporulation [187]. In conclusion, regardless of presence or absence of osmoprotectant like glycine betaine in high osmolarity

medium, expression of sporulation genes was dramatically reduced compared to the control sample.

Down regulation of genes involved in chemotaxis during glucose starvation (section 6.2) and during multiple stress conditions including continuous growth at high salt (section 6.3) were discussed earlier. In the particular experiment discussed here *B. subtilis* was exposed to a combination of both glucose limitation and high salt, which resulted in down regulation of majority of the genes involved in chemotaxis. However, we cannot distinguish to which both entities contributed to the total reduction of genes involved in chemotaxis. Furthermore, expression of chemotaxis genes was restored in the presence of glycine betaine.

Genes responsible for utilization of alternate carbon sources are usually up-regulated under glucose starvation or limitation. In the current study, there was a strong down regulation of the genes associated to the utilization of alternate carbon sources during continuous growth at high salt in comparison to the reference and osmoprotection conditions. This might reflect the fact that under all conditions cells were already experiencing glucose/ energy limitation and thus the extra strain for producing more proline and the respective enzymes, this required further down-regulation of other genes. However, there was no indication of starvation from the adenylate energy charge (AEC) of the cell (Table 3, measurements performed by Hanna Meyer, Greifswald) during growth at high salinity. This might indicate that the *B. subtilis* prioritizes the protection from high salinity rather than seeking for an alternative carbon source during simultaneous glucose limitation and high salt adaptation growth. Producing large amounts of proline consequently from the utilization of limited available glucose fulfilled this priority. Surprisingly for unknown reasons during osmoprotection the ATP level was approximately three folds less compared to the reference and salt stress conditions.

**Table 3: Intracellular levels of adenylates and adenylate energy charge (AEC) for non-stressed, salt-stressed and osmoprotected *B. subtilis*. (Measurements performed by Hanna Meyer, Greifswald)**

	Unit	Reference*	Salt stress*	Osmoprotection*
AMP	mmol g <sub>DCW</sub> <sup>-1</sup>	1.86 ± 0.49	1.53 ± 1.42	1.85 ± 0.64
ADP	mmol g <sub>DCW</sub> <sup>-1</sup>	4.08 ± 0.62	5.79 ± 3.25	3.18 ± 0.51
ATP	mmol g <sub>DCW</sub> <sup>-1</sup>	19.20 ± 2.29	17.40 ± 6.77	6.67 ± 0.85

---

#### 6.4.1 Multi-omics investigation of central carbon metabolism

---

Both glucose limitation and growth at high salt are interconnected as the osmoprotectant proline is synthesized from glucose. To this regard, comprehensive understanding of the central carbon metabolism and biosynthesis of proline is important. Comprehensive understanding of a pathway is possible when all the molecules associated to the pathway were measured, so in the current study a multi-omics investigation was performed and this provided unique insights into the adaptational response at a systems level.

The key prerequisite for the growth at high salt was to amass high amount of intracellular proline which was achieved by the strong up-regulation of both *proHJ* transcription and ProHJ protein levels more than fivefold (see Figure 24) [68, 78]. Though both the enzymes were transcribed from the same promoter controlled by SigA and mRNA levels should thus be equal, but the abundances of proteins were quite different with ProH being three fold higher in abundance compared to ProJ. This apparent difference could arise from the position of ProJ being at the distal end of the operon or due to translation or stability of the proteins. The main outcome from the stoichiometry measurement of the proteins was that ProA present in excess in any given condition over the rest of the proline biosynthetic enzymes (Figure 28). This observation solves the riddle how *B. subtilis* can satisfy its need for ProA during high salt growth even if its gene is not subject to osmotic regulation in contrast to those of encoding ProH and ProJ. High abundance of ProA complies with the demands of the anabolic proline biosynthesis and the high amounts of proline required for osmoprotection. It is clear from the data that key enzymes show a high abundance within their specific pathway. This could be shown for ProA, which is required for the anabolic and osmotically induced proline biosynthesis in *B. subtilis*, and was always present in higher abundance compared to the rest of the proline biosynthetic enzymes. This strategy might give an added advantage to *B. subtilis* to adapt quickly to sudden osmotic up shift in the environment.

In the presence of the both osmoprotectant glycine betaine and 1.2 M NaCl the proline levels were close to those in control cells in the absence of high salt. Moreover mRNA levels of *proJ* and *proH* were also low as in control cells, but protein levels remained well above those observed in non-stressed control cells. Moreover in the presence of glycine betaine, ProA was

present in significantly higher amounts (three fold) although its expression is not osmotically regulated. This discrepancy of mRNA and proline pools at the one side and protein levels on the other side could be explained by the ability of GB to stabilize proteins that were produced basal level expression of the the *proHJ* operon by the major sigma factor SigA [9]. However, the low levels of proline observed in the presence of large amounts of ProH and ProJ would also imply an impact of GB on activity of both proteins. A potential effect of GB on protein stabilization was discussed in detail in section 6.4.2. Though regulation of activity of ProJ and ProH has not been explored in detail in *B. subtilis* yet, presence of protein and absence of proline suggests a possibility for activity regulation.

It was shown that the intracellular concentration of proline can reach 400mM [188] during growth at 1 M NaCl and this amount is even higher during sudden osmotic up shift to 0.4 M NaCl [76]. Amassing high amount of intracellular proline also creates a concentration gradient which facilitates the leakage of proline to extracellular environment which is also observed in *E. coli* [189]. Proline leakage has also been shown to occur in *B. subtilis* and the excreted proline is sequestered mainly by the OpuE transporter to ensure effective osmoprotection [72, 188]. In the current study, OpuE was also strongly up-regulated at high salinity to sequester extracellular proline. The process of proline leakage and the re-import via the OpuE transporter might also offer fine-tuning the intracellular turgor pressure for *B. subtilis* at high salinity [188]. *B. subtilis* can also take up proline and use it as a nutrient, which is then catabolized to glutamate by the PutBCP proteins with PutP constituting the second importer of the extracellular proline besides OpuE. In the presence of external proline, PutR promotes the expression of the *putBCP* gene cluster [8]. The *putBCP* gene cluster is repressed in the presence of other amino acids by CodY (by replacing PutR) which is in turn dependent on the metabolite GTP [190]. In the current study, simultaneous glucose limitation and growth at high salinity induced the expression of the *putBCP* genes to tenfold or higher to intermediate levels. However, this is in contrast to Moses *et al.* 2012 [83] who described for shake flask cultures that the high amount proline produced as an osmoprotectant at high salinity did not induce the *putBCP* gene cluster since such a induction would be futile. This apparent difference could be the result by the very low amounts of intracellular GTP (measurements performed by Hanna Meyer, Greifswald) levels during high salinity in chemostat cultures (Figure 49) that could lead to release of CodY from the *putBCP* gene cluster and thereby causing the derepression and intermediate expression of the *putBCP* operon; on the other hand excess extracellular proline present due to leakage might also contribute to the PutR mediated intermediate expression of the *putBCP* gene cluster. To

conclude, the co-occurrence of low GTP amount and high intracellular proline levels might facilitate the intermediary activation of the proline catabolic pathway.

In the presence of glycine betaine (GB), the gene cluster *putBCP* was strongly down regulated (see Figure 24) compared to the growth at high salinity. This could be explained by the greatly reduced intracellular proline levels in the presence of glycine betaine, which would diminish leakage thereby preventing activation of the PutR protein. During osmoprotection, enhanced repression by CodY was unlikely because the amount of GTP decreased even further in the presence of GB.

Figure 49: GTP concentration obtained from LC-MS measurements of the intracellular metabolome analysis from the samples involved in the current study. GTP concentrations were significantly reduced in the presence of high salt (1.2 M NaCl) and during osmoprotection (1.2 M NaCl + GB). (Measurements performed by Hanna Meyer, Greifswald)

Regardless of the condition analyzed in this study; the reference, growth at high salinity and during the osmoprotection: the flux through central skeleton of CCM was relatively stable (see Figure 26). But the mRNA and proteins that are involved in CCM differed strongly between these conditions. This implies that molecules necessary to run the system itself were dynamically regulated to maintain a homeostatic flux under the conditions tested.

With few exceptions, both transcriptome and proteome were in good agreement across the conditions tested. The majority of the glycolytic enzymes showed a slight increase in the abundance during growth at high salt compared to the reference sample (see Figure 24). This observation was also made partially in the TCA cycle for the components of the CitB, Icd and Odh complex. All these changes likely occur to provide enough 2-oxoglutarate to produce high amounts of proline to provide osmoprotection to the cell. However, the slight increase in the enzyme abundance in the CCM did not result in increase in the flux of CCM during growth at

high salt. All these changes occur amid maintaining a constant flux through the CCM in the presence of high salt (see fig Figure 26). The advantage of higher abundance of enzymes during high salt was compensated by the loss in enzyme activity (see Figure 27) of the enzymes due to high  $K^+$  intracellular concentration [76] at high salinity. This hypothesis was tested on two key enzymes of the CCM such as Pgi, Icd, Pyk (data not shown) and Mdh (data not shown), where both the enzymes exhibited 56% (for Pgi) and 41% (for Icd) loss of enzyme activity at 600 mM  $K^+$  ion concentration. Out of these enzymes, Pgi and Icd were proven to be required for altered flux rerouting [191] providing an alternate path for carbon flux in various conditions. The increase in protein abundance to compensate the loss of enzyme activity could be an adaptational strategy to achieve a constant flux adopted by *B. subtilis* when there is a combination of glucose limitation and high salinity. However it is not clear how this flux balancing is achieved, it could be due to the dependency of the pleiotropic regulators (CcpA, CodY etc..) on the intracellular metabolites (ATP, GTP, FBP etc) to regulate their target genes. Key metabolites for global control of metabolism such as ATP, GTP and fructose-1,6-bisphosphate (F1,6BP) were strongly decreased in the presence of salt stress. This suggested that metabolic control is crucial to maintain steady state of flux.

Concurrent presence of proline with elevated  $K^+$  concentration was not able to restore the loss in enzyme activity. However, 650 mM of glycine betaine was able to restore the enzyme activity partially. This advantage of glycine betaine over proline might be the reason behind the better osmoprotection offered by glycine betaine. Addition of glycine betaine prevented the accumulation of proline as an osmoprotectant, as accumulation of *de novo* synthesized substrates (like proline [76, 192]) are slow due to transcription and translation of the components involved and more cost intensive than uptake of a substrate present in the environment. Thus, the naturally available osmoprotectants like glycine betaine are readily taken up by existing or newly synthesized transporters [193].

Though glycine betaine is metabolically inert in *B. subtilis*, it could affect several proteins in central carbon metabolism. Interestingly, most of the significantly affected proteins in the presence of GB were known to form complexes. In this case the metabolon (CitZ-Icd-Mdh-PckA-YtsJ) formed within the TCA cycle [59] were present in higher abundance which were in non-correlation with their respective gene expression. This was also observed in the SdhABC complex as well. Pertaining to the idea of protein complex stabilization in the presence of GB, it is worth discussing about a probable protein complex between ProJ, ProA and ProH; a similar pattern was observed for these proteins as well, where the mRNA levels remain unchanged but

the protein levels were up-regulated. Moreover the intermediates produced by the pathway are known to be lethal to the cellular metabolism in *B. subtilis* [78] and other organisms[194, 195]; unless these intermediates are channeled within a complex, the cellular physiology might not endure the high amount of proline generated as an osmoprotectant. A further investigation involving the co-purification of these proteins is necessary to prove the existence of this potential complex.

In *E. coli*, increase in osmolality causes the loss of intracellular water thereby decreasing the space between the biomolecules, this leads to crowding and increase in biomolecular (proteins and nucleic acid) concentration *in vivo* [196]. Testing such a hypothesis *in vitro* also resulted in crowding of biomolecules which subsequently reduced the biomolecular diffusion rates and had thermodynamically driven biomolecular assembly and aggregation [197, 198]. In the overcrowded circumstances *in vivo* proline is more effective than GB in preventing aggregations [199, 200] probably due to the ability of proline to interact with proteins [199] whereas GB cannot interact with proteins as it is devoid of hydrogen bond donor [201]. Due to the overcrowding at high osmolality in conjunction with inability of GB to interact with proteins, protein aggregation (via preferential interactions) might be favored. These physiochemical properties of GB could be the major reason behind the novel changes including the increased protein content and the protein complex stabilization phenomenon.

To conclude, protein stoichiometry measurements in conjunction with other omics technologies provided unique and unbiased insights into the regulatory mechanisms adopted by *B. subtilis* under varying growth conditions. Though glycine betaine provided osmoprotection, the molecular phenotype of these osmoprotected cells differed from that of the reference condition and the growth at high salinity. These observations raised further questions about the physiological changes induced by glycine betaine apart from being an osmoprotectant.

---

### 6.4.2 Effect of glycine betaine during exponential growth and osmoprotection

---

To understand the effect of the GB on a global proteome scale and its impact on the protein stoichiometry (possible aggregations), shake flask experiments were performed in SMM media where glucose was present in excess. Unlike the chemostat experiments, in shake flask experiments the growth rates were variable and dependent on the media composition. Several earlier studies addressed the biophysical characteristics of proline [202] and GB *in vivo* and *in vitro* and their impact on biomolecular interactions [196] and protein stabilization [199, 200, 203]. Extending these findings, in the current study effects of GB during normal growth and as an osmoprotectant and proline at high salinity were investigated to decipher the role of GB and proline on the cellular physiology at the protein level.

Significant differences in the growth rate were observed in all the conditions tested (see Figure 29). The growth rates were in the decreasing order of SMM + GB > SMM > SMM + 1 mM GB + 1.2 M NaCl > SMM + 1.2 M NaCl. Though GB itself is metabolically inert in *B. subtilis*, the difference in the growth rate in the presence GB over the *de novo* synthesized proline could be mainly explained by the biophysical characteristic of GB. In *E. coli*, accumulation of osmoprotectants like GB or proline extends the growth rate of the osmotically stressed cells by fundamentally altering the cellular water distribution via the free cytoplasmic water (unbound water to macromolecules) and the water bound to the macromolecules [196, 204, 205]. Higher amounts of free cytoplasmic water promote higher growth rate and vice versa as observed in yeast [206] and *E. coli* [196]. Glycine betaine can be accumulated up to intracellular concentrations of  $\geq 500$  mM by *B. subtilis* during high salinity [70, 76]. Osmoprotectants like GB are known to increase free cytoplasmic water more than other osmolytes at similar concentrations [196]. This specific effect of GB is achieved by its ability to remain in the free cytoplasmic water as it cannot bind to the macromolecules [201] thereby increasing osmolality of the free cytoplasmic water and offering better osmoprotection compared to other osmolytes like proline or trehalose.

Pertaining to the differences in the growth rate, significant changes in the global proteome were observed (see fig Figure 30). Most of the observed changes correlate to the improved growth rate in the presence of GB; the changes include up regulation of proteins involved in translation, biosynthesis and acquisition of nucleic acids and amino acids. The changes that are not directly correlated to the growth rate affect proteins of the SigB regulon. In the presence of GB during

normal growth or at high salinity, a down regulation of members of SigB regulon compared to the respective exponential growing reference conditions could be observed. During the exponential growth the cells might not experience any stress, so the expression of SigB regulon could be at basal level through promoter leakage (for some proteins), and for some unknown reason this minimal effect is even abolished in the presence of GB. The proteins that were commonly up-regulated in the presence of GB during normal growth and during osmoprotection (Figure 33) were mainly involved in anabolic processes such as biosynthesis/acquisition of amino acids and nucleotides. This increase in anabolic proteins is related to increase in growth rate that is in turn increased in the presence of GB due to its biophysical properties.

Protein complexes in CCM were not stabilized in the presence of GB in the shake flask samples unlike in the chemostat (see Figure 37). The stabilization effect by GB can thus possibly depend on any of the three reasons. 1) the effect of GB on protein complex stabilization could be more prominent when GB is present in the media for longer period (in chemostat which is greater than 48 hours) compared to shake flask (less than 10 hours), 2) influence of GB over protein stabilization could be higher in slow growing cells (samples cultivated in chemostats) in comparison to fast growing cells (samples cultivated in shake flasks), 3) finally protein stabilization by GB could be pronounced during energy limitation (chemostat) in comparison to excess energy (shake flask). However it is not clear with the current data what could be the potential reason for GB to stabilize the proteins. Many of the unstable proteins (see Table 2 and Figure 34) that were thought to be the targets of ClpCP protease upon entry into starvation phase in *B. subtilis* [1] were present in higher amount in the presence of GB. Most of these target proteins of the protease ClpCP are the first-committed-step enzymes for biosynthesis of aromatic and branched chain amino acids, cell wall precursors, purines, and pyrimidines [1]. Association of these unstable proteins to the anabolic pathways renders the *B. subtilis* a growth advantage in the presence of GB. As GB is metabolically inert in *B. subtilis* the global changes induced by GB could be primarily due to biophysical properties of GB that indirectly led to the changes associated with the metabolism.

Absolute quantification of CCM proteins in the shake flask cultivated samples (high glucose) had revealed only minor changes either in the presence of GB or high salinity or osmoprotection; this is in contrast to the glucose limited chemostat cultivated samples where major changes were observed in the CCM proteins. The fundamental differences between both the conditions (shake flask and chemostat) are glucose concentrations and growth rates. Expression of the glycolytic enzymes primarily depends on the availability of glucose. Presence of excess amount of glucose

allowed the higher expression of glycolytic enzymes in shake flask compared to that of chemostat cultivated samples (see Figure 35); this effect was observed both in the reference condition and at high salinity. The existing high amount of glucose and glycolytic proteins were sufficient to synthesize large amounts of proline required for osmoprotection at high salinity rendering the CCM proteins majorly unaffected. Higher abundance of glycolytic enzymes due to excess glucose could have abrogated the process of flux balancing (loss of enzyme activity compensated by the increase in enzyme concentration) that is observed in glucose limited chemostat at high salinity (see section 6.4.1).

Though the rest of the protein complexes were not stabilized in CCM during osmoprotection in the shake flask, the presumed protein complex between ProA-ProJ-ProH was stabilized in shake flasks reproducing the result from the chemostat cultivations (see Figure 37). In a similar experimental set up Hoffmann *et al.* 2012 [207] it was shown that addition of 1 mM GB at high salinity completely abolished the synthesis of proline, this result suggested that there might not be any expression (mRNA and protein) of *proHJ* in the presence of GB. However, the current results suggest that indeed the proteins are available in both shake flask and chemostat experimental setup even in the presence of GB, but they might be enzymatically inactive to produce proline. These results also imply there might a potential regulation of ProH/J activity involved that could respond to high salinity and osmoprotectants like GB.

### 6.4.3 The effect of ProH, ProJ over-expression and glutamate supplementation

The proteins ProH and ProJ play a key role in providing osmoprotection to the *B. subtilis* by producing high amounts of proline (intracellular concentration of 400 mM [188]) as an osmoprotectant [9]. Glutamate is the precursor required for the synthesis of proline for both anabolic and osmoprotective purposes. Glutamate was decreased (approximately 450 mM to 100 mM) approximately four fold with increasing salinity (up to 1 M NaCl) in the medium to synthesize proline [9]. Despite the production of high amounts of proline and utilization of glutamate, the cells grow at least four times slower than the reference condition. The above result raised two questions: 1) whether the ProJ and ProH proteins are the limiting factors that hinder the growth?; 2) whether the available glutamate is sufficient for the synthesis of the optimal amount of proline? To address these two questions over expression of ProJ and ProH and supplementation of glutamate during high salinity were performed for the better understanding of the dynamics of osmoprotection in *B. subtilis* that involves proline as an osmoprotectant. These experiments were performed in a joint effort with the group of Erhard Bremer in Marburg and I was responsible for the proteome analysis in these studies.

Over expression of *proHJ* was achieved by introducing a combination of point mutations into a wild type SigA promoter of *proHJ* to generate the M10 promoter (consensus SigA promoter) in the strain MDB28 (see Figure 39). On par with the TreA activity assay of *proHJ* fusions in the strain M10, absolute protein quantification also showed over expression of ProJ and ProH. Over expression of both these proteins did not provide better osmoprotection. This lack of improved osmoprotection of *B. subtilis* amid the over expression of ProJ and ProH could be due to several reasons. Even though the concentration of these proteins increased significantly in the MDB28 compared to that of wild type JH642 strain the proline concentrations did not increase proportionally with the increase in the enzyme concentration as indicated in Table 4 (Data obtained from the doctoral dissertation of Monika Dolezal, Marburg/Lahn, 2006). This could be explained by two possible reasons; 1) a possible activity regulation of ProJ and ProH that was already discussed in the section 6.4.1, 2) the other possibility is leakage of proline to the extracellular environment via an unknown system because the mechanosensitive channels (MscL and MscS) were proven to be not involved in the leakage of proline [188]. The unknown system could be a passive carrier/transporter as the washing of cells with conventional buffers like TE buffer resulted in loss of total intracellular proline as the cell are osmotically down shocked (data not shown). All these possible explanations point out to the fact that higher concentrations of proline could lead to endo-osmosis due to higher intracellular turgor pressure that is also

deleterious to the cellular physiology. Hence, *B. subtilis* keeps the proline concentration at optimal levels required for its protection and the rest synthesis is either enzymatically inhibited or leaked to extracellular environment, which could be re-imported via PutP or OpuE transporter system. This re-import mechanism of proline could also play a crucial role in fine-tuning the turgor pressure of *B. subtilis*.

**Table 4:** TreA activity of *proHJ* fusion strain and their corresponding intracellular proline concentrations in the strains JH642 (wild type) and M10 (*proHJ* over expression) under normal growth (0 M NaCl) and at moderate salinity (0.4 M NaCl). \*Data obtained from the doctoral dissertation of Monika Dolezal, Marburg/Lahn, 2006.

	ProJ and ProH expression (TreA activity nmol min <sup>-1</sup> mg Protein <sup>-1</sup> )		Proline amount(μmol g TG <sup>-1</sup> )	
	0 M NaCl	0.4 M NaCl	0 M NaCl	0.4 M NaCl
<b>JH642</b>	14	42	1.6	37
<b>MDB28</b>	602	1043	24	122

We also assessed the effect of ProHJ overexpression on the levels of the other proline biosynthetic enzymes during low and high osmolarity. ProA which has a dual role in both anabolic and osmoprotective synthesis of proline was increased by two fold whereas the co-expressed protein ProB was unchanged or slightly decreased during high salinity in comparison to none-stressed cells (see Figure 42), this was observed in both normal strain (JH642) and ProHJ over expression strain (MDB28). However, in a similar experimental setup the *B. subtilis* wild type strain 168 Trp<sup>+</sup>, the mRNA levels of *proA* and *proB* (see Figure 43) were not significantly increased in the presence of high salinity in comparison to the none-stressed cells. Unchanged mRNA expression and increase in amount of only the protein ProA might once again indicate a potential complex formation between ProJ-ProA-ProH that might be stabilized when required (in this case during high salinity). The amount of ProA was concomitantly elevated along with the increased expression of ProJ and ProH indicating the protection of ProA in the complex. Interestingly the secondary analogue of the ProH enzyme, ProG was up-regulated by approximately two fold during high salinity, although the exact regulatory mechanism of ProG is unknown. As expected the anabolic route of the proline biosynthesis involving ProB and ProI proteins was unchanged during high salinity. Over expression of ProJ and ProH did not affect the levels of proteins involved in the CCM.

Addition of external glutamate only partially improved the osmoprotection capabilities owing to the fact that further increase in the amount of proline (which is already at 400 mM of

intracellular proline at 1 M NaCl [83, 188]) could also be deleterious due to increase in turgor pressure. ProJ and ProH were unaffected upon addition of glutamate; however the anabolic route of proline biosynthesis (ProA, ProB and ProI) was up-regulated in the presence of glutamate which indicates a feed forward activation of this pathway in the presence of the substrate glutamate. Furthermore, supplementation with glutamate induced some changes to the proteins in the CCM, some of which were not reported earlier. To our knowledge there were two independent studies that investigated the effect of glutamate on the global transcriptome [208, 209]. Schilling *et al.* (2007) employed the CGSE medium (glucose, succinate and glutamate) and reported the transcriptional profiles and the flux associated with the proteins involved in the CCM. The authors indicated several changes in CCM that are subjected to metabolic regulation mediated by post-translational changes. Bang-Ce C *et al.* 2009 performed a glucose limited chemostat supplemented with glutamate, valine and glutamine independently and performed global transcriptome analysis. Due to glucose limiting conditions, the gluconeogenic pathway was activated much stronger in the presence of glutamate indicating the entry of glutamate into the TCA and thereby expressing gluconeogenic enzymes. In the case of experiments performed by Schilling *et al.* (2007) a high glucose concentration of 0.5% was used comparable with the current study. The major difference was the presence of succinate along with glutamate in the medium. The data from Schilling *et al.* 2007 showed an increase in the overflow metabolism especially the acetate production was increased in the presence of glutamate.

In the current study a significant increase in YtsJ (malic enzyme) indicates a possible increase of pyruvate that might lead to the production overflow metabolites like acetate and lactate. This observation is also supported by the significant decrease in the CitZ and CitB, which marks the entry of acetyl Co-A into TCA cycle. Measurement of metabolome and flux of the CCM under these conditions would provide more information. Increase in the overflow metabolism and decreased channeling of pyruvate to TCA cycle implies that presence of high glucose favors overflow metabolism which is aggravated further in the presence of glutamate, which also takes care of replenishing TCA cycle intermediates. Simultaneous use of multiples energy sources (in this case glucose via glycolysis and glutamate via TCA and glycolysis) demonstrates the versatile and unique regulatory mechanisms associated to the CCM proteins to efficiently utilize the available energy sources which are often limited in the natural habitat for *B. subtilis*.

In the presence of glucose the GltA and GltB enzymes (both subunits of GOGAT) are responsible for converting 2-oxoglutarate to glutamate. Expression of *gltAB* genes is controlled by the LysR-type transcription activator GltC in the presence of glucose [46]. GOGAT is an

iron-containing enzyme which is regulated upon the availability of iron [210]. Iron mediated expression of GOGAT is brought about by the non-coding RNA FsrA which blocks the translation of GltAB by binding to the mRNA of *gltAB* upon iron limitation [211]. Due to high salt mediated iron limitation (discussed in the section 6.4) a strong repression of *gltAB* was observed in the current experiment and also in the section 6.4.2. This repression of *gltAB* also continued in the presence of glutamate probably due to the binding and subsequent inactivation of GltC by RocG in the presence of glutamate [212].

Entry of glutamate into TCA cycle is catalyzed by the functional glutamate dehydrogenase (RocG) which is activated by transcription factors RocR and AhrC in the presence of nitrogen source like arginine and repressed in the presence of glucose by CcpA [3]. Therefore, in the presence of both glucose and glutamate can repress and express *rocG* respectively. Under similar experimental conditions a basal level expression of *rocG* gene was observed by Schilling *et al.* 2007, which was sufficient to convert excess glutamate to 2-oxoglutarate that can replenish the reduced intermediates of the TCA cycle. Some of the changes observed in the CCM upon addition of glutamate however raised further questions; changes such as upregulation of most of the glycolytic enzymes (PfkA, all the proteins from the *cggR* operon) in the presence of glutamate – suggesting a possible increase in flux through glycolysis. In order to comprehensively understand the concomitant effect of glucose and glutamate on the metabolic pathways a detailed global transcriptome and proteome analysis would be necessary.

To summarize, overexpression of ProH and ProJ enzymes did not improve the osmoprotection efficiency and this lack of improvement could be due to possible activity regulation of ProH and ProJ or proline leakage to extra cellular environment via unknown mechanism. Proline alone is not the best osmoprotectant compared to glycine betaine (as GB improves growth rate due to its biophysical properties, see section 6.4.1), so supplementation of additional glutamate or proline could not dramatically increase the osmoprotection efficiency or improve the growth rate.

## 8. SUPPLEMENTARY TABLES

**Table S5: List of genes belonging to the corresponding regulons used for the transcriptome analysis of bi-phase batch and tri-phase fed-batch fermentations.**

Gene name	BSU number	Regulon	Regulator	Mode of action	Description
leuD	BSU28250	CcpA regulon	CcpA_pos	activation	3-isopropylmalate dehydratase small subunit
leuC	BSU28260	CcpA regulon	CcpA_pos	activation	3-isopropylmalate dehydratase large subunit
leuB	BSU28270	CcpA regulon	CcpA_pos	activation	3-isopropylmalate dehydrogenase
leuA	BSU28280	CcpA regulon	CcpA_pos	activation	2-isopropylmalate synthase
ilvC	BSU28290	CcpA regulon	CcpA_pos	activation	Ketol-acid reductoisomerase
ilvH	BSU28300	CcpA regulon	CcpA_pos	activation	Acetolactate synthase small subunit
ilvB	BSU28310	CcpA regulon	CcpA_pos	activation	Acetolactate synthase large subunit
ackA	BSU29470	CcpA regulon	CcpA_pos	activation	Acetate kinase
pta	BSU37660	CcpA regulon	CcpA_pos	activation	Phosphate acetyltransferase
glpQ	BSU02130	CcpA regulon	CcpA_neg	repression	Glycerophosphoryl diester phosphodiesterase
glpT	BSU02140	CcpA regulon	CcpA_neg	repression	Glycerol-3-phosphate transporter
amyE	BSU03040	CcpA regulon	CcpA_neg	repression	Alpha-amylase
phrC	BSU03780	CcpA regulon	CcpA_neg	repression	Phosphatase rapC inhibitor
dctP	BSU04470	CcpA regulon	CcpA_neg	repression	C4-dicarboxylate transport protein
rsbV	BSU04710	CcpA regulon	CcpA_neg	repression	Anti-sigma-B factor antagonist
rsbW	BSU04720	CcpA regulon	CcpA_neg	repression	Serine-protein kinase rsbW
sigB	BSU04730	CcpA regulon	CcpA_neg	repression	RNA polymerase sigma-B factor
rsbX	BSU04740	CcpA regulon	CcpA_neg	repression	Phosphoserine phosphatase rsbX
gmuB	BSU05810	CcpA regulon	CcpA_neg	repression	Oligo-beta-mannoside-specific phosphotransferase
gmuA	BSU05820	CcpA regulon	CcpA_neg	repression	Oligo-beta-mannoside-specific phosphotransferase
gmuC	BSU05830	CcpA regulon	CcpA_neg	repression	Oligo-beta-mannoside permease IIC component
gmuD	BSU05840	CcpA regulon	CcpA_neg	repression	6-phospho-beta-glucosidase gmuD
gmuR	BSU05850	CcpA regulon	CcpA_neg	repression	HTH-type transcriptional regulator GmuR
gmuE	BSU05860	CcpA regulon	CcpA_neg	repression	Putative fructokinase
gmuF	BSU05870	CcpA regulon	CcpA_neg	repression	Probable mannose-6-phosphate isomerase gmuF
gmuG	BSU05880	CcpA regulon	CcpA_neg	repression	Mannan endo-1,4-beta-mannosidase
yesM	BSU06950	CcpA regulon	CcpA_neg	repression	Sensor histidine kinase yesM
pel	BSU07560	CcpA regulon	CcpA_neg	repression	Pectate lyase
citM	BSU07610	CcpA regulon	CcpA_neg	repression	Mg (2+)/citrate complex secondary transporter
yfiN	BSU07620	CcpA regulon	CcpA_neg	repression	Uncharacterized protein yfiN
treP	BSU07800	CcpA regulon	CcpA_neg	repression	PTS system trehalose-specific EIIBC component
treA	BSU07810	CcpA regulon	CcpA_neg	repression	Trehalose-6-phosphate hydrolase
treR	BSU07820	CcpA regulon	CcpA_neg	repression	Trehalose operon transcriptional repressor
yfkN	BSU07840	CcpA regulon	CcpA_neg	repression	Trifunctional nucleotide phosphoesterase protein YfkN
acoA	BSU08060	CcpA regulon	CcpA_neg	repression	Acetoin:2,6-dichlorophenolindophenol oxidoreductase
acoB	BSU08070	CcpA regulon	CcpA_neg	repression	Acetoin:2,6-dichlorophenolindophenol oxidoreductase
acoC	BSU08080	CcpA regulon	CcpA_neg	repression	Dihydrolipoyllysine-residue acetyltransferase component
acoL	BSU08090	CcpA regulon	CcpA_neg	repression	Dihydrolipoyl dehydrogenase
acoR	BSU08100	CcpA regulon	CcpA_neg	repression	Acetoin dehydrogenase operon transcriptional activator
sspH	BSU08110	CcpA regulon	CcpA_neg	repression	Small, acid-soluble spore protein H
malA	BSU08180	CcpA regulon	CcpA_neg	repression	Maltose-6'-phosphate glucosidase
glvR	BSU08190	CcpA regulon	CcpA_neg	repression	HTH-type transcriptional regulator GlvR
malP	BSU08200	CcpA regulon	CcpA_neg	repression	PTS system maltose-specific EIICB component [Includes:
glpF	BSU09280	CcpA regulon	CcpA_neg	repression	Glycerol uptake facilitator protein
glpK	BSU09290	CcpA regulon	CcpA_neg	repression	Glycerol kinase
glpD	BSU09300	CcpA regulon	CcpA_neg	repression	Aerobic glycerol-3-phosphate dehydrogenase
yhaR	BSU09880	CcpA regulon	CcpA_neg	repression	Putative enoyl-CoA hydratase/isomerase yhaR
lcfB	BSU10270	CcpA regulon	CcpA_neg	repression	Long-chain-fatty-acid--CoA ligase
uxaC	BSU12300	CcpA regulon	CcpA_neg	repression	Uronate isomerase
yjmB	BSU12310	CcpA regulon	CcpA_neg	repression	Uncharacterized symporter yjmB
yjmC	BSU12320	CcpA regulon	CcpA_neg	repression	Uncharacterized oxidoreductase yjmC

Gene name	BSU number	Regulon	Regulator	Mode of action	Description
yjmD	BSU12330	CcpA regulon	CcpA_neg	repression	Uncharacterized zinc-type alcohol dehydrogenase-like
uxuA	BSU12340	CcpA regulon	CcpA_neg	repression	Mannonate dehydratase
yjmF	BSU12350	CcpA regulon	CcpA_neg	repression	Uncharacterized oxidoreductase uxuB
exuT	BSU12360	CcpA regulon	CcpA_neg	repression	Hexuronate transporter
exuR	BSU12370	CcpA regulon	CcpA_neg	repression	Probable HTH-type transcriptional repressor ExuR
uxaB	BSU12380	CcpA regulon	CcpA_neg	repression	Altronate oxidoreductase
uxaA	BSU12390	CcpA regulon	CcpA_neg	repression	Altronate hydrolase
ldt	BSU14040	CcpA regulon	CcpA_neg	repression	Putative L,D-transpeptidase YkuD
abbA	BSU14120	CcpA regulon	CcpA_neg	repression	Uncharacterized protein ykzF
ykuL	BSU14130	CcpA regulon	CcpA_neg	repression	CBS domain-containing protein ykuL
ccpC	BSU14140	CcpA regulon	CcpA_neg	repression	Uncharacterized HTH-type transcriptional regulator
ctaC	BSU14890	CcpA regulon	CcpA_neg	repression	Cytochrome c oxidase subunit 2
ylbP	BSU15100	CcpA regulon	CcpA_neg	repression	Uncharacterized N-acetyltransferase ylbP
sucC	BSU16090	CcpA regulon	CcpA_neg	repression	Succinyl-CoA ligase [ADP-forming] subunit beta
sucD	BSU16100	CcpA regulon	CcpA_neg	repression	Succinyl-CoA ligase [ADP-forming] subunit alpha
xynP	BSU17570	CcpA regulon	CcpA_neg	repression	Uncharacterized symporter ynaJ
xynB	BSU17580	CcpA regulon	CcpA_neg	repression	Beta-xylosidase
xylA	BSU17600	CcpA regulon	CcpA_neg	repression	Xylose isomerase
xylB	BSU17610	CcpA regulon	CcpA_neg	repression	Xylulose kinase
yozM	BSU18960	CcpA regulon	CcpA_neg	repression	Prophage-derived-like uncharacterized protein yozM
yobO	BSU19030	CcpA regulon	CcpA_neg	repression	Putative phage-related protein yobO
odhB	BSU19360	CcpA regulon	CcpA_neg	repression	Dihydrolipoyllysine-residue succinyltransferase
odhA	BSU19370	CcpA regulon	CcpA_neg	repression	2-oxoglutarate dehydrogenase E1 component
cwlS	BSU19410	CcpA regulon	CcpA_neg	repression	D-gamma-glutamyl-meso-diaminopimelic acid
yopL	BSU20850	CcpA regulon	CcpA_neg	repression	SPBc2 prophage-derived uncharacterized protein yopL
kdgT	BSU22090	CcpA regulon	CcpA_neg	repression	2-keto-3-deoxygluconate permease
kdgA	BSU22100	CcpA regulon	CcpA_neg	repression	KHG/KDPG aldolase [Includes: 4-hydroxy-2-
kdgK	BSU22110	CcpA regulon	CcpA_neg	repression	2-dehydro-3-deoxygluconokinase
kdgR	BSU22120	CcpA regulon	CcpA_neg	repression	HTH-type transcriptional regulator KdgR
kduI	BSU22130	CcpA regulon	CcpA_neg	repression	4-deoxy-L-threo-5-hexosulose-uronate ketol-isomerase
kduD	BSU22140	CcpA regulon	CcpA_neg	repression	2-dehydro-3-deoxy-D-gluconate 5-dehydrogenase
qcrA	BSU22560	CcpA regulon	CcpA_neg	repression	Menaquinol-cytochrome c reductase iron-sulfur subunit
ypiF	BSU22570	CcpA regulon	CcpA_neg	repression	Uncharacterized protein ypiF
resE	BSU23110	CcpA regulon	CcpA_neg	repression	Sensor histidine kinase resE
resD	BSU23120	CcpA regulon	CcpA_neg	repression	Transcriptional regulatory protein resD
resC	BSU23130	CcpA regulon	CcpA_neg	repression	Cytochrome c biogenesis protein ResC
resB	BSU23140	CcpA regulon	CcpA_neg	repression	Cytochrome c biogenesis protein resB
resA	BSU23150	CcpA regulon	CcpA_neg	repression	Thiol-disulfide oxidoreductase resA
yqiQ	BSU24120	CcpA regulon	CcpA_neg	repression	Methylisocitrate lyase
mmgE	BSU24130	CcpA regulon	CcpA_neg	repression	2-methylcitrate dehydratase
mmgD	BSU24140	CcpA regulon	CcpA_neg	repression	2-methylcitrate synthase
mmgC	BSU24150	CcpA regulon	CcpA_neg	repression	Acyl-CoA dehydrogenase
mmgB	BSU24160	CcpA regulon	CcpA_neg	repression	Probable 3-hydroxybutyryl-CoA dehydrogenase
mmgA	BSU24170	CcpA regulon	CcpA_neg	repression	Acetyl-CoA acetyltransferase
cccA	BSU25190	CcpA regulon	CcpA_neg	repression	Cytochrome c-550

## **9. AFFIDAVIT / ERKLÄRUNG**

---

---

Hiermit erkläre ich, dass diese Arbeit bisher von mir weder an der Mathematisch-Naturwissenschaftlichen Fakultät der Ernst-Moritz-Arndt-Universität Greifswald noch einer anderen wissenschaftlichen Einrichtung zum Zwecke der Promotion eingereicht wurde.

Ferner erkläre ich, dass ich diese Arbeit selbständig verfasst und keine anderen als die darin angegebenen Hilfsmittel und Hilfen benutzt und keine Textabschnitte eines Dritten ohne Kennzeichnung übernommen habe.

Greifswald, date: 24.04.2014

Praveen Kumar Sappa

## 10. CURRICULUM VITAE

---

### Personal Details

Name	Praveen Kumar Sappa
Date of Birth	05.08.1986
Place of Birth	Tadepalligudem
Nationality	Indian

### Educational Qualifications

**1. Higher Secondary School (2001-2003):** Vikas Junior college, Rajahmundry, India

**3. Bachelor in Science (2003-2006):** Andhra University, Visakhapatnam, India

**4. Masters in Biotechnology (2006-2008):** University of Hyderabad, Hyderabad, India

**Doctoral Study (since 08/2008):** Doctoral student at Interfakultary Institute for Genetics and Functional Genomics, Dept. of Functional Genomics, Ernst-Moritz-Arndt-University, Greifswald, Germany

Greifswald, Date: 24.04.2014

Praveen Kumar Sappa

## 11.2 POSTERS

---

Transcriptome Analysis of Batch and Fed-Batch Fermentations.

Sappa PK, Knoke B, Mäder U, Steil L, Reuss M, Hecker M, and Völker U.

2009, May, Vienna, Austria.

Absolute quantitation of central carbon metabolic proteins in Osmotic stressed *Bacillus subtilis* - deployment of QconCAT strategy.

Sappa PK, Kohlstedt M, Meyer H, Burian M, Mäder U, Hoffmann T, Lalk M, Bremer E, Wittmann C, Völker U.

EuPA-BSPR 2012, June, Glasgow, UK. (awarded Deutsche Gesellschaft für Proteomforschung travel scholarship)

Multi-omics based investigation of central carbon metabolism of glucose starved *Bacillus subtilis* under osmotic stress and osmoprotection.

Sappa PK, Kohlstedt M, Meyer H, Burian M, Mäder U, Hoffmann T, Lalk M, Bremer E, Wittmann C, Völker U.

Proteome forum Berlin - 2013, April, Berlin, Germany. (awarded Deutsche Gesellschaft für Proteomforschung travel scholarship)

## **12. ACKNOWLEDGEMENTS**

---

I am greatly thankful to Prof. Uwe Völker for giving me this wonderful opportunity to pursue my doctoral studies. I would like to express my gratitude for his immense support at work and beyond which made my stay in Greifswald a great pleasure. His remarkable professional and straightforward approach at sorting out things is a striking quality that I deeply admire.

I would like to especially thank Leif Steil for his support and guidance throughout my work in the lab. He was the one person I used to depend on for advice regardless of the kind of problem and he never gave up without a tough fight. I am extremely thankful to Ulrike Mäder for her timely guidance and help through several collaborative projects I was involved. Her meticulous approach towards the details really helped me to correct my mistakes several times. I would also like to thank Elke Hammer, Frank Schmidt and George Homuth for their helpful discussions and advices. It was my great pleasure working with Dhople and learning key aspects of mass spectrometry from his remarkable experience.

I would like to thank Ulf Leibal (from Rostock), Michael Kohlstedt (from Braunschweig), Hanna Meyer and Sandra Maß for not only being my collaborators but also for their incredible welcoming and friendly relationship. The great fun we had on several business trips was priceless. I would like to thank all the people involved in BaCell-SysMO phase I and phase II for their collaboration and BMBF (Bundesministerium für Bildung und Forschung) for the financial support.

I am greatly thankful to all my friends, current and former colleagues in the lab for creating a wonderful environment at work place. I would like to thank especially Marc Schaffer, Marc Burian, Tej, Priyanka, Hermann, Nico, Henrike, Kristin, Martin, Ravi, Lars, Manu, Gourav, Annette, Franzi, Stefan, Tobi, Abdullah, Malek and all other members in the lab. I would like to thank all the TA's for their timely help especially Anja, Jette and Katrin.

Last but not least I am indebted to my parents, my sister and my wife for their infinite care, love and support throughout my life.
