VEGF	Vascular Endothelial Growth Factor
VUV	Vacuum Ultra Violet
YAP	Yes Associated Protein

1. Introduction

1.1 Human Skin

The human skin is the largest organ of the body. The skin and its accessory structure make up the integumentary system which protects the body against mechanical, physical and chemical stress [1]. The skin is composed of two main layers: the epidermis, made of closely packed epithelial cells, and the dermis, made of dense, irregular connective tissue that houses blood vessels, hair follicles, sweat glands, and other structures. Beneath the dermis lies the hypodermis, which is composed mainly of loose connective and fatty tissues. Figure 1.1 illustrates the human skin comprising the epidermis, dermis and hypodermis. The epidermis is divided into the layers stratum basale, stratum spinosum, stratum granulosum and stratum corneum [2]. Except stratum basale, the cells in all the other epidermal layers are called keratinocytes, consist >90% of the total epidermis and are at various differentiation stages in different layers. During this process of differentiation, the keratinocytes flatten more and more and at the stratum corneum they lose their cell nuclei [2]. The stratum basale is a single cell layer primarily made of basal cells. Two other cell types are found interspersed among basal cells, i.e., merkel cell and melanocytes. The dermis might be considered as the core of integumentary system and contains blood and lymph vessels, nerves, and other structures, such as hair follicles and sweat glands. The dermis is made of two layers of connective tissue that compose an interconnected mesh of elastin and collagenous fibers, produced by fibroblasts [2]. In our study, we focused on the two major cell types of epidermis and dermis, keratinocytes and fibroblasts, respectively.

1. Introduction

Figure 1.1 Layers of human skin, comprised of epidermis, dermis and hypodermis. The figure is adapted from Open Stax, Anatomy and physiology [2].

1.2 Wound Healing

Wound healing is one of the well-orchestrated complex processes within the human body and consists of four interdependent and overlapping phases namely hemostasis, inflammation, proliferation and remodeling [3, 4]. Figure 1.2 illustrates the sequential stages of wound healing. Over these four intertwined phases, spatial and temporal synchronization of various cell types resolves the wound. The hemostasis phase is characterized by platelet aggregation, degranulation, vascular constriction and fibrin formation. The inflammatory phase is caused by invading microorganisms and starts with the infiltration of neutrophils at the wound bed followed by macrophages and leucocytes. The proliferation phase is highly overlapping with the inflammatory phase and is characterized by angiogenesis where new blood vessels are formed, collagen synthesis for extracellular matrix deposition and re-epithelialization. The final stage of wound healing is remodeling, where the collagen and vascular structure are restructured. In case, a cutaneous wound is formed, wounds are healing anywhere from within a few days up to a few weeks. However, when wounds do not follow these “routine steps” and do not show any sign of resolution even after 4 weeks, are designated as non-healing or chronic wounds. It is often referred that a prolonged inflammatory phase leads to chronic wounds [5]. We will now discuss the acute and chronic wound separately.

Figure 1.2 Sequential illustration of wound healing stages. The figure is adapted and modified from www.biodermis.com and Akbik et al. [6].

1.3 Acute Wounds

Acute wounds result from surgical wounds or trauma such as burns, excoriations, animal bites etc. [7]. A complete wound healing is characterized by four interdependent and overlapping phases where different cell types like keratinocytes, fibroblasts, immune surveillance cells, microvascular cells play an important role in tissue repair and regeneration [8, 9]. Immediately after injury, platelets aggregate at the wound site, begin a hemostatic reaction and induces a blood clotting cascade which constrains excessive blood loss. Platelets attracts the first horde of immune cells like neutrophils, leucocytes and monocytes/macrophages by releasing key chemotactic molecules like PDGF, TGF- α 1 and α 2 [10, 11]. Neutrophils are the first to appear at the wound site in large numbers. Once in the wound site, the integrin receptors at the surface of neutrophils enhance cell matrix interactions and enables the neutrophils to kill and phagocytose bacteria and wound debris [11, 12]. Mast cells at the wound site also release histamines, leukotrienes, cytokines and proteases which are additional signals for leukocyte recruitment [13]. Monocytes are the most important immune cells for the later stages of inflammation resolution. At the wound site, they are recruited in response to chemotactic factors like MCP-1[14] and MIP-1 [15] and are differentiated to macrophages. Extracellular matrix degradation products like collagen and fibronectin fragments also attract monocytes [16]. Macrophages mediate the subsequent obliteration by killing remaining pathogenic organisms, scavenging tissue debris and killing any remaining neutrophils which have not initiated apoptosis [11]. Macrophages are the source of cytokines and growth factors that initiate cell migration, proliferation and re-epithelialization. First keratinocytes at the wound edge change their shape, become flatter

1. Introduction

and elongated [3]. Important signaling molecules like FGF-7, EGF, TGF- α , TGF- β , GM-CSF, matrix metalloproteinase and several cytokines induce keratinocyte migration and proliferation [3, 4]. These cytokines and growth factors also activate fibroblasts which proliferate and migrate into the granulation tissue, initiates collagen formation and wound constriction [17]. Fibroblasts can transform into myofibroblasts and contract the connective tissue at the wound site [3]. Concurrently, paracrine and autocrine interactions between different cell types, ECM and peripheral nerves leads to a hypoxic environment at the wound site, which is the major trigger for angiogenesis [10]. Hypoxic environment stimulates the production of HIF-1 α from fibroblasts [18, 19], keratinocytes [20], macrophages [21, 22] and vascular endothelial cells [23]. The release of pro angiogenic factors from macrophages and fibroblasts like VEGF, VEGF-A, FGF-2, PDGF and TGF- β 1 and the metabolic switch in endothelial cells promote neovascularization [24]. Finally the fibroblasts proliferate and deposit ECM which sustains the newly formed blood vessels [19, 25]. The last and the longest phase of acute wound healing is the remodeling phase [3]. In this stage, the granulation tissue is diminished, metalloproteinase released from fibroblasts and macrophages destroy collagen III in the granulation tissue and replaces it with collagen I [10]. This stage can last up to a few months. The acute wound healing is illustrated in figure 1.3.

Figure 1.3 Illustration of relevant cell types and soluble mediators engaged in acute wound. The figure is adapted from Openja et al [26].

1.4 Chronic Wounds

Chronic wounds do not adhere to the standard course of wound healing. Venous leg ulcers, ischemic leg ulcer, diabetic foot ulcer and pressure sores are the most common examples of chronic wounds. Despite differences in molecular etiology, most of these chronic wounds share similar features with stalled inflammation, persistent infection, resistant microbial biofilm formation at the wound site and dermal cells failing to respond to a reparative stimulus [27-30]. Chronic wounds are characterized by prolonged and persistent infiltration of macrophages [31]. Loots et al., observed a higher population of CD8+T cells compared to CD4+ T cells, which resulted in an increased infiltration of macrophages, B cells and plasma cells in the chronic wound bed compared to acute wounds [31]. The reason for the increased infiltration of immune cells could be attributed to the higher level of pro inflammatory cytokines and growth factors at the chronic wound environment [32-35]. Healing ulcers correlated with the reduction of pro inflammatory cytokines like IL-1, IL-6 and TNF- α in wound fluid; [34] but also with TGF-beta increase in wound fluid [33]. Moreover, a distinct cytokine and chemokine expression signature have been also investigated. Chronic wound fluids showed a differential expression of well-known wound healing biomolecules like IL-1 β , PDGF, VEGF, bFGF, TGF- α , IL-6, IL-8, and IL-18 compared to acute wound fluids. However, lesser reported molecules in context of wound healing like RANTES, IL-17A, I-TAC, IL-23, IP-10 and EPO were differentially expressed in the two wound states [36]. Chronic wounds also display higher load of bacterial colonization at the wound site. Bacterial infection is an extrinsic factor that delays wound healing [37]. Bacteria and the infiltrated immune cells produce proteases which degrade the ECM and the growth factors [38]. Biofilms are prevalent in chronic wound [8, 39] and delays epithelialization [40].

Another characteristics of chronic wounds are phenotypic abnormalities of epidermis and dermis-derived cells [38]. Compared to healthy skin fibroblasts, fibroblasts isolated from chronic wounds show decreased mortality and have lower mitogenic potential in response to PDGF-AB, EGF, bFGF and IGF [38]. Keratinocytes also show lower migratory potential in chronic wounds. This phenomenon has been attributed to the lower production of laminin 332, which is an important substrate of ECM and therefore could be a reason for delayed re-epithelialization [41]. These keratinocytes also display an increased activation of A-catenin/c-myc pathway and do not express keratin 10 and 2, markers of differentiation [42]. Chronic wounds are also infiltrated with senescent fibroblasts. Diabetic patients often show matrix glycation, which could be a reason for premature senescence in fibroblasts, angiogenic sprout formation, decreased cell proliferation and migration [38, 43]. On one hand, matrix glycation can disrupt the matrix assembly and the interaction between collagen and the matrix binding partners. On the other hand, high glucose in diabetic patients induces the production of high MMPs by fibroblasts, macrophages and endothelial cells, thus contributing to matrix instability and therefore further delaying the wound healing [38, 44, 45].

1. Introduction

Low levels of ROS are essential in all phases of wound healing. Low concentration of ROS are essential for the fight against invading microorganisms or redox signaling resulting in cell survival signaling [46]. Physiological concentration of ROS drives cell proliferation, migration and wound repair [46]. A balance between antioxidants and reactive species is therefore significant for wound healing. Elevated and sustained oxidative stress is frequently associated with chronic wounds. This is majorly due to the elevated production of ROS by infiltrated immune cells, which could lead to an imbalance between redox species and antioxidants in the wound resulting in oxidative stress at the wound site [47]. Wound fluids collected from chronic wound patients also show a decrease in antioxidants, in fact chronic wounds show a lower expression of natural antioxidants Vitamin A and E [48] and glutathione [49]. Elevated ROS levels can damage endothelial cells, thus inhibiting angiogenesis [50]. High ROS levels at the chronic wound milieu can induce the expression of MMPs in fibroblasts and inactivate the TIMPs, thus ensuing in a highly proteolytic environment in the wound site and finally delaying wound healing [47, 51-54]. The chronic wound healing is shown in figure 1.4.

Figure 1.4 Illustration of chronic wound. Adapted from Larouche et al. [55].

1.5 Signal Transduction

Signal transduction is the process by which a physical or chemical stimulus is transmitted through a cell as a series of molecular events. External stimuli can be physico-chemical (like pH, oxidative stress, temperature) or biological (cytokines, chemokines etc.) [56]. Most often, the environmental signal is first processed by a cell membrane bound receptor protein. These receptors have an intracellular and extracellular domain. The signals bind to the 'binding site' of the extracellular domain and generates a signaling cascade. The first signals are often called primary messengers; upon binding of these messengers the receptor-ligand complex undergoes a structural change. This structural change is not sufficient to elicit a response from the cells, as the numbers of membrane bound receptors are very few. However, secondary messengers transmit the signal from the receptor-ligand complex and can affect the cascade by two ways; first they are small molecules which can freely diffuse in the nucleus and influence the transcription factors for downstream gene expression. Secondly, they can be amplified significantly and can work as the 'input' for other signaling pathways leading to multiple cross talk. ROS play a central role as secondary messengers and determines cell fate and several other cellular processes.

1.6 HIPPO Signaling Pathway

The HIPPO signaling pathway was first identified in *Drosophila melanogaster* and is a regulator of organ size, proliferation and is highly conserved in vertebrates and arthropods [57]. The core HIPPO cascade which consists of four kinase cassette, was first identified through genetic screens for tumor suppressor genes in *Drosophila*. The cascade includes Warts (Wts) [58, 59], the WW domain containing protein Salvador (Sav1/WW45) [60, 61], the Ste20- like protein kinase Hippo (Hpo) [62-64] and the adaptor protein Mob as tumor suppressor (Mats) [65]. In mammals, the core kinase cascade contains two Hpo homologs which are Mst1 and Mst2, two Wts homologs (LATS1 and LATS 2), one Sav homolog (WW45 or Sav1) and two Mats homologs (MOBKL1A and MOBKL1B) [57].

The Hippo pathway can be stimulated by multiple types of cellular stress, including mechanical stress, and reactive oxygen species [66]. Mst1/2 bind to their regulatory protein WW45/Sav1 and activates it which in turn phosphorylates and activates LATS1/2 kinases [67, 68]. Mst1/2 also activates and phosphorylates MOB1A/B [69]. The MOB1A/B-LATS1/2 complex in turn phosphorylates the two major transcriptional coactivators of the HIPPO cascade, Yes associated protein (YAP) and transcriptional coactivator with PDZ-binding motif (TAZ) [70-72]. YAP and TAZ have HXRXXS/T motifs which are phosphorylated by LATS1/2 kinases [73]. Upon phosphorylation, these two effectors undergo cytoplasmic sequestration or ubiquitin mediated protein degradation by binding to 14-3-3 proteins [72, 74].

1. Introduction

When LATS1/2 is inactive (de-phosphorylated), YAP/TAZ are not phosphorylated and translocate to the nucleus (figure 1.5 right part). In the nucleus, YAP/TAZ bind to TEAD domain family members (TEAD 1-4) and mediate the transcription of target genes such as Connective Tissue Growth Factor (CTGF) and Cysteine rich angiogenic inducer 61 (Cyr61) [75]. These downstream genes code for CCN family proteins regulating cell growth, proliferation, migration and survival [74, 76-78]. These extracellular matrix associated angiogenic regulators are heparin binding proteins, share 47% amino acid identity [79, 80] and are synthesized during cutaneous wound healing in dermal fibroblasts [81]. YAP, CTGF and Cyr61 are the main focus for this thesis. Apart from TEAD family transcription factors, YAP/TAZ interacts with several other transcription factors like Smad family members (1, 2/3, 7), RUNT related transcription factors (RUNX1, RUNX2), T box transcription factors (TBX5) and p73 [79].

Figure 1.5 On/off state of HIPPO signaling pathway. The figure is adapted from Boopathy et al. [79].

There are numerous examples of redox-mediated activation of HIPPO signaling pathway. MST-1 is activated upon oxidative stress and phosphorylates FOXO3 leading to neuronal cell death due to FOXO3 mediated Bim expression [82]. YAP also mediates ROS triggered signaling. In cardiomyocytes, YAP acts as a transcriptional co-activator of FOXO1 and upregulates the expression of antioxidant genes like catalase and Mn-SOD [83]. GABP (an ETS family member) mediated YAP expression is also correlated with oxidative stress in the liver [84]. YAP also acts as a functional link between HIPPO and PI3K-mTOR pathway. YAP inhibits PTEN by inducing miR-29 and thus activates the mTOR signaling pathway which is involved in cellular growth and proliferation [85]. Furthermore, YAP binds to HIF-1 α and promotes sustained HIF-1 α protein stability [86]. Moreover, YAP and TAZ are also involved in wound healing and tissue regeneration. The localization of YAP and TAZ in

1. Introduction

nucleus is important for cutaneous wound healing and knockdown of these two genes can cause potential delay in wound closure [87]. In the basal layer of epithelial cells, expression of YAP and TAZ increases post wounding; however wound healing is markedly decreased in YAP/TAZ double conditional knockout mice [88]. Taken together, these results already indicate the role of YAP-TAZ in cutaneous wound healing.

CTGF is a 40 kDA, matricellular protein and has been reported to interact with several cytokines and growth factors like IGF-1, BMP-4, BMP-7, TGF- β and VEGF [89]. It is also described that CTGF interacts with cell-surface receptors and integrin receptors [89]. Moreover, CTGF interacts with matrix proteins such as fibronectin or heparine sulphate proteoglycans [89]. Due to its ability to interact with several growth factors, cytokines and receptors, CTGF possess the potential to regulate several biological processes including cell migration, adhesion, proliferation, angiogenesis, early wound healing and repair [90-93]. Several studies provide evidence that CTGF is linked to wound healing cascade. For example, application of recombinant human CTGF (10-100 ng/cm²) in non-human primate burn wound induced faster healing and proliferation compared to the control group [94]. Topical application of CTGF on diabetic rodent wounds showed a faster wound closure rate, accumulation of collagen IV at the wound site and increased expression of alpha smooth muscle actin expression and macrophage infiltration [95]. CTGF is induced in tissue repair and constitutive CTGF expression is a hallmark of fibrogenesis. Kapoor et al. also observed that CTGF promoter activity is absent in normal skin, but post wounding the promoter activity is induced in myofibroblasts [96].

Like CTGF, Cyr61 has also been reported to affect several cellular activities including cell migration, proliferation, angiogenesis and apoptosis [81, 90, 97, 98]. Cyr61 is a cell adhesion protein and binds to several integrin receptors including $\alpha\beta3$, $\alpha\beta5$, $\alpha\text{IIb}\beta3$, $\alpha6\beta1$, and $\alpha\text{M}\beta2$ in different cell types [99]. Cyr61 is involved in cell migration of fibroblasts and epithelial cells. Zhang et al. showed that Cyr61 mediates PDGF-induced cell migration via Cyr61-integrin-FAK signaling cascade in smooth muscle cells [100]. It also regulates matrix remodeling by inducing metalloproteinases during angiogenesis and wound healing in dermal fibroblasts [101]. Moreover, it has been also shown to induce fibroblast senescence in response to cutaneous wound healing to restrain fibrosis during tissue repair [102]. Oxidative stress plays an important role in activation of Cyr61 downstream the HIPPO cascade. Qin et al. found that Cyr61 expression is induced by oxidative stress and that a positive feedback loop continues to generate ROS and upregulate Cyr61 in fibroblasts [103].

Present literature suggests that reactive species is an important modulator of HIPPO signaling cascade and downstream angiogenic proteins. Therefore, in this study we wanted to investigate the role of HIPPO signaling in wound healing upon plasma treatment.

Figure 1.6 Simplified version of HIPPO signaling pathway. The figure is combined and adapted from Boopathy et al. [79], Zhang et al. [86], Tumaneng et al. [85] and Mao et al. [104].

1.7 Plasma

Plasma is the fourth fundamental state of matter after solid, liquid and gas and was first described by the American physicist and chemist Irving Langmuir in the nineteen-twenties [105]. Irvine Langmuir first coined the term in 1928 [106]. Plasma is a partially or completely ionized gas. Gas atoms collide with other gas atoms and free electrons and becomes ionized; this happens when the kinetic energy of the collision is higher than the ionization energy. Upon increase of gas temperature, the kinetic energy also increases which results in higher probability of ionized collision [107]. Therefore, the transition from gas to plasma is quite transient and continuous. Figure 1.7 describes the transition from solid to plasma. Visible matters such as lightning, *Aurora borealis*, stars etc. are in state of plasma. In fact, it is supposed, that 99 % of the matter in the universe is plasma. Plasma can be manmade and is nowadays exploited in a variety of processes e.g. environmental remediation, agriculture or surface modification to name a few. Plasma medicine is the latest application of plasma research. It is a new field at the intersection of physics, engineering, biology and medicine. Plasma is generated by energizing gas up to a critical point at which electrons dissociate from atoms [56]. The resulting partially ionized gas contains charged particles, while the overall charge remains electrically neutral. Typical particles being generated include ions, electrons, or reactive oxygen and nitrogen species (ROS/RNS) [56]. Electric and magnetic fields, light (visible, infrared, UV), and neutral particles are also generated [108]. The physicochemical properties of plasma is complex and depends upon a variety of

1. Introduction

parameters which includes the type and composition of the gas or gas mixture used for plasma generation, the applied energy and electrode configuration, the pressure, and the environment [108].

Figure 1.7 States of matter: generation of plasma. Plasma is the fourth state of matter after solid, liquid and gas. Plasma is composed of large number of unbound charged particles.

In the history of plasma technology thermal plasma with temperature higher than 80°C has been used for tissue ablation, destruction and sterilization purposes [109]. In thermal plasma, temperatures of the electrons and ions are equal and remains in thermal equilibrium [110]. However, for medical purposes, since the 1990s, technologies for stable and reproducible plasma generation at low temperature under atmospheric conditions are available on a larger scale, facilitating the generation of so-called non-thermal plasma or cold atmospheric plasma (CAP). Most cold atmospheric plasmas (CAP) for biomedical applications are generated by applying electrical energy to a not directly biologically effective gas (argon, helium, oxygen, nitrogen, air, or gas mixtures). The electrical energy is mostly transmitted to excite free electrons whereas the majority of gas atoms, molecules and ions remain in a low energy state resulting in a low plasma temperature [111]. In contrast to thermal plasma, CAP is characterized by low degree of ionization (about 1%). Hot free electrons ($T_e \geq 10^4 \text{ K}$) which are responsible for the ionization initiation are surrounded by neutral gas molecules with relatively low temperatures ($T_g \leq 10^3 \text{ K}$) [112]. Therefore, lower energy levels are transferred to the ions, molecules and atoms of the plasma leading to a composition which is not at thermal equilibrium and the total plasma temperature is a few hundred K [113]. For biomedical applications, plasma sources which emits minimum thermal output and does not exceed 40°C at target site are considered for medical purposes [114].

Excited atoms and molecules interact with each other for the open atmospheric conditions and with neighboring media and generate primary and secondary reactive species with

1. Introduction

biological potential at the genome, transcriptome and proteome level. Electromagnetic radiation ((UV/VUV, visible light, IR/heat, electric fields) is also emitted [111]. The generation of reactive species vastly depend on each plasma source and device parameters like working gas, power input and temperature [115]. Figure 1.8 illustrates the generation of short- and long-lived redox species by plasma.

Figure 1.8 CAP generates reactive species with biological potential. This figure is adapted from Weltmann et al. [116].

1.8 Plasma Medicine

Plasma medicine has emerged as one of the exciting new field at the interface of physics and life sciences. CAP, due to its operation at atmospheric pressure and low temperature is apt for treatment of viable tissues and thus has become a focus of medical research over the past years [117]. The modern era of plasma medicine started with the application of CAP on cultivated cells which induced separation of cells from a uniformed cell structure without killing the cells. This was the first direction for a non-lethal selective application of CAP on living cells [118].

Plasma medicine follows an interdisciplinary research approach, where physics describes the physical parameters of plasma production, life science investigates the basic effect of CAP on microorganisms, tissues and eukaryotic cells and finally plasma medicine aims to describe the effect of cold plasma in clinical use [119]. A variety of different CAP devices has been developed for research and therapeutic applications. While some of them are already used in clinics as certified medical devices, some CAP devices are still used in benches. Majorly, there are two different type of CAP discharges, direct (Dielectric Barrier Discharge: DBD) and indirect (APPJ: Atmospheric Pressure Plasma Jet). Figure 1.9 illustrates the two types of plasma source. With the DBD, plasma is ignited in the gap

1. Introduction

between an isolated dielectric high voltage electrode and the tissue to be treated. Here, the tissue/cells work as the counter electrode. Most of the DBD devices use atmospheric air as the feed gas [111]. In contrast, APPJ consists of a gas nozzle with one or two electrodes. The plasma is ignited inside the nozzle and transported outside to the object with a preassembled working gas (mostly neutral gas or gas mixture) [111]. Since 2013, four devices have been medically certified for its use in clinical purposes: Argon gas operated Jet based devices kINPen MED (Neoplas Tools GmbH) and SteriPlas (ADTEC, Hunslow, UK) as well as the DBD-based devices PlasmaDerm (CINOGY GmbH Duderstadt, Germany) and plasma care (terraplasma medical GmbH Garching, Germany), the latter two using atmospheric air as working gas [108].

Figure 1.9 Volume DBD and Plasma Jet in contact with fingertip. The figure is adapted from Weltmann et al. [116].

Various studies have focused on the anti-microbial, anti-inflammatory, anti-neoplastic and wound healing promoting properties of CAP [120-123]. Several *in vitro* studies have elucidated CAP mediated effective inactivation of bacteria and have shown its potential as an effective tool for disinfection [107, 124-128]. The antiseptic properties of CAP have also been shown in clinics by microbial load reduction in wounds and tissues [129-133].

One of the starting points in plasma medicine focused on the use of CAP in wound healing due to its antimicrobial activity. Several experimental *in vitro* studies demonstrate a direct impact of CAP on cell proliferation and migration as well as on angiogenesis [134-142]. The results of this basic research details that CAP mediated wound healing does not only depend on the microbial load reduction, but also on the direct stimulation of tissue regeneration [119]. CAP treatment leads to upregulation of Nrf2-Keap-1 signaling axis which in turn stabilizes the architecture of F-actin cytoskeleton and focal adhesions and increases granulation tissue formation and matrix deposition [123, 143]. Activation of the Nrf2 also mediates the upregulation and secretion of inflammatory molecules and therefore recruit immune cells for which activates the wound healing signaling [123]. In fact, CAP supports angiogenesis by stimulating the secretion of Keratinocyte Growth Factor (KGF),

1. Introduction

Vascular Endothelial growth factor (VEGF), basic Fibroblast Growth Factor (bFGF), Epidermal Growth Factor (EGF) etc [136, 137, 144, 145]. Several groups and clinicians now are interested in the role of CAP in acute and chronic wound management in vivo and in patient trials. A study of burn wounds in mice showed that plasma treatment enhanced angiogenesis [146]. Full-thickness cutaneous wound healing was found to be accelerated after exposure to CAP as well [142]. In several randomized pre-clinical trials and case studies, CAP has shown to reduce the wound size faster than the established treatments and accelerate wound healing processes as a preliminary result [116, 147]. CAP is also able to influence the inflammatory and immune cell signature in a chronic wound environment. Taken together, CAP treatment leads to an accelerated healing in acute and chronic wound [123]. Besides wound healing, other CAP application in dermatology have been reported, mainly in the treatment of pathogen-based and/or inflammatory skin irritations and diseases [109, 148, 149]. The role of CAP in dentistry also falls under the umbrella of plasma medicine; possible dental application of CAP include inactivation and removal of biofilm on teeth, disinfection of tooth root canal, plasma-assisted cleaning and optimization of tooth and implant surfaces to improve bone integration [150].

1.9 The atmospheric pressure argon plasma jet *kINPen MED*

The *kINPen MED*® is a commercially available atmospheric pressure argon plasma jet. Its concentric, light-weighted, and pen-like design was developed for biomedical applications and allows precise and arbitrary 3D movements. Due to its easy handling, this device can be used for both a direct treatment of cold plasma on the cells and indirect treatment of liquids [151]. The hand-held unit is operated using a power supply and a gas supply unit. In this work *kINPen MED* was used as the only plasma source. The electrical safety of the *kINPen* was certified and complies with EU standards [151]. This is the first jet worldwide to be accredited as a medical device class IIa according to European Council Directive 93/42/EEC for use in wound treatment and this device lacks mutagenic and genotoxic effects [151-153]. In its metal housing a central rod like capillary is shielded by a dielectric quartz capillary connected to a grounded ring electrode. Figure 1.10 depicts the physical structure of *kINPen MED*. The plasma is generated by applying a sinusoidal voltage (2–6 kVpp) with a frequency of 1.0–1.1 MHz to the central electrode (power: <3.5 W in the hand-held unit). The typical plasma effluent length is 9–12 mm and 1 mm in diameter [151]. The complete physical parameters of *kINPen MED* is provided in table 1.1. High spatial and temporal optical resolution of the plasma revealed that it propagates in a bullet-like manner [154]. Argon is primarily used as feed gas, but other molecular gases can be also admixed [155]. In particular, the plasma in the effluent region interacts with the ambient air and generates non-reactive species (like H₂O₂, ozone) or radical species (like hydroxyl radical, nitrogen monoxide) [156]. A gas curtain can also be used to shield the plasma, which generates a more controlled environment influencing the plasma chemistry in contact with liquids [157].

1. Introduction

Figure 1.10 Atmospheric pressure plasma jet kINPen MED. Physical structure and application on skin. The figure is adapted from Bekeschus et al. [151].

Table 1. 1 Physical parameters of kINPen MED. The table is adapted from Bekeschus et al [151].

Properties	kINPen MED
Recommended feed gas and flux	Argon (5 ± 1 l/min)
Frequency	1 MHz
Feed gas flow control	Yes (Integrated)
Mode of operation	Pulsed 2.5 kHz
Duty cycle	Plasma on/off = 1:1
Power	<8W of the whole system <3.5W of the handheld device
Typical effluent length	9-11 mm
Recommended working distance	8-10 mm
Temperature at recommended working distance	35-38°C
UV irradiation at working distance	UV A : 5-15 μ W/ cm ² UV B : 5-15 μ W/ cm ²
Plasma stabilization during plasma generation	Automatic: PLL-circuit

1.10 Wound healing is subject to redox control

The redox environment of wound site has an important influence in cutaneous wound healing. ROS are critical secondary messengers that orchestrate the wound healing processes by regulating the immune response, angiogenesis and optimal perfusion of blood at wound site [158]. Redox state at the wound site regulates thrombosis and blood coagulation [158, 159]. The inflammatory stage is profoundly affected by the redox environment; H₂O₂ directly regulates the monocyte function which are recruited at the wound site [160]. ROS induce the production of MIP-1A, MIP-2 and MCP-1 [161, 162]; chemotactic molecules which recruits immune cells at the wound site. H₂O₂ also modulates leucocyte adhesion molecule expression [163] and transcriptional expression of MCSF-1, which drives the monocyte adherence to the extracellular matrix [164]. Several chemokines at the wound site respond to ROS. ROS induce CCR5 and CXCR4 mRNA expression [165]. Low concentration of H₂O₂ sensitizes the mRNA expression of CCR2, CCR5, and CXCR4 mRNA [165]. H₂O₂ also increases cell migration in response to MIP1 [165]. Re-epithelialization is also influenced by redox species; at lower concentration, ROS induces epithelial cell proliferation and migration [166, 167]. Studies have shown that, H₂O₂ supports wound healing in keratinocytes by inducing VEGF production [168]. In fact, Roy et al. showed that even though, high doses of H₂O₂ have an adverse effect on wound healing; at lower doses it induces FAK phosphorylation at wound edge tissues and drives H₂O₂ mediated angiogenesis in vivo [169]. Studies have also shown that H₂O₂ induced-VEGF-A transcription is driven by the Ras-Raf-MEK1-ERK1/2 pathway [170]. CAP generates a plethora of redox species, which similar to H₂O₂ influence the physiological stages of wound healing i.e. cell migration [171], viability [172, 173], proliferation [174], inflammation [175] and dermal regeneration and re-epithelialization [176]. CAP also triggers the nuclear translocation of Nrf2, basic leucine zipper (bZIP) protein that regulates the expression of antioxidant genes against redox damage [143]. Upon its translocation and activation, Nrf2 and its downstream targets affect angiogenesis [120], oxidation of lipid layers [143] and TGF- β signaling during wound healing [177].

1.11 Aim of the work

During the past few years, plasma medicine has emerged as an important field in biomedical science. Cold atmospheric plasma generates a mixture of reactive oxygen and nitrogen species, including singlet oxygen, atomic oxygen, hydroxyl radicals, and hydrogen peroxide, as major (secondary) contributors. In recent years, CAP has been used for the management of acute and chronic wounds in clinics; however, the mechanistic insight of CAP-mediated wound healing responses remain still largely unexplored.

In clinics, through observational study, efficacy of KINPen MED in wound healing has been demonstrated [151]. In fact, plasma-mediated wound closure has also been observed in monoculture of keratinocytes by an accelerated production of growth factors and neovascularization [145]. CAP could also promote proliferation and migration of human dermal fibroblasts as well as production of cytokines and collagen [135]. Yet, for simulation of cross talk of diverse cell types in wounds, it has to be investigated how CAP affects single cell types and their cross talk. However, studies on the effect of CAP on synergistic interaction of dermal keratinocytes and fibroblasts remain scarce. Activation of anti-oxidant pathways upon cold plasma treatment has been also described in keratinocytes and animal model [123, 178]. Nevertheless, not much studies have focused on the regenerative and remodeling signaling potential of cold plasma. Therefore, this study aimed to investigate the stimulatory potential of cold plasma and addressed the following questions:

1. How does CAP affect the coculture of dermal keratinocytes and fibroblasts in terms of cell migration and cell viability/metabolic activity?
2. How does CAP affect the regenerative signaling (HIPPO signaling) pathway and extracellular matrix and adhesion molecules?
3. What is the impact of CAP on the paracrine interaction between keratinocytes and fibroblasts?

To this end, we first optimized the coculture of keratinocytes and dermal fibroblasts *in vitro*. Next, we performed cell viability studies and ‘scratch assays’ to characterize and distinguish plasma activities on skin cell monocultures and the coculture of keratinocytes and fibroblasts. Subsequently, plasma-modulated regenerative signaling molecules and extracellular matrix and adhesion molecules were identified. Finally, this research aimed to study the paracrine cross talk between keratinocytes and fibroblasts post plasma treatment. Altogether, this thesis contributed to a more detailed picture on plasma-mediated molecular mechanisms in wound healing.

3. Methods

3.1 Cell Culture

Human skin keratinocytes HaCaT (Cell Lines Service, catalog no. 300493) and immortalized skin fibroblast cell line GM00637 (GM Fbs, Coriell Institute, New Jersey, USA) were cultured in Roswell Park Memorial Institute 1640 cell culture medium (RPMI 1640), supplemented with 10% fetal calf serum (FCS), 0.1 mg/ml penicillin/streptomycin, and 2 mM L-glutamine (Pan Biotech) at 37°C, 95% humidity and 5% CO₂. For sub cultivation of cells, GM Fbs were washed with 5 ml of PBS-EDTA (0.5mM EDTA) and HaCaT cells were incubated with the mentioned volume of PBS-EDTA for 10 minutes. Afterwards, both the cell lines were trypsinized with 3 ml Trypsin-EDTA (Corning), detached cells were suspended with 5 ml culture medium. Then, the cells were centrifuged at 500 g for 3 minutes, supernatant was discarded and cell pellets were suspended in 5 ml new culture medium. For GM fibroblasts, a starting density of $2-4 \times 10^6$ cells and for HaCaT cells a density of 2×10^6 cells were seeded in a new culture flask of 75 cm², supplemented with 10 ml culture medium. The sub cultivation was performed twice in a week.

3.2 Plasma Source

CAP treatment was performed using an atmospheric argon plasma jet kINPen MED (Neoplas tools, Greifswald, Germany). The electrical safety of the kINPen was certified and complies with EU standards [151]. This is the first jet worldwide to be accredited as a medical device class IIa according to European Council Directive 93/42/EEC for use in wound treatment and this device lacks mutagenic and genotoxic effects [151-153]. The simple pen like design was developed for biomedical applications. The jet was operated at a voltage of 2-6 kVpp and a frequency of 1.0-1.1 MHz. The gas flow rate was set at 5 Standard Liter per Minute (SLM) and the plasma had a visible plume of 9-12 mm in length and 1 mm in diameter. For our experiments, we operated the jet only with argon gas.

3.3 Indirect Plasma treatment

The plasma jet kINPen Med, as depicted in figure 3.1 was operated with argon gas at a flow rate of 5 SLM (standard liters/minute) as controlled by a Mass Flow Controller (MFC). The kINPen Med was fixed with a computer controlled xyz table (CNC Machines, Germany) that conducted a P shaped movement over the liquid surface to ensure equal distribution of plasma generated species in the liquid. In most cases, 5 ml of RPMI 1640 supplemented with 1 % FCS in a 60-mm dish was treated for 10, 30 and 60 s depending on the experimental type. CAP treated media was used immediately to treat the cells for further experiments. Cells incubated with untreated RPMI medium served as negative controls for all experiments.

Figure 3.1 kINPen MED. a. Picture of indirect plasma treatment with kINPen MED. b. Moving track of the kINPen MED. 5 mL cell culture medium in a 60 mm dish was plasma-treated with the jet along the P-shaped track by a computer controlled xyz table.

3.4 Direct Plasma Treatment:

For direct plasma treatment, cells were seeded in a 96 well plate; before the treatment only 50 μ l of cell culture volume was kept per well. Then the kINPen MED was operated with argon gas at a gas flow rate of 5 SLM for 10 and 30 seconds. For control, no treatment was performed. The kINPen was fixed with a computer controlled xyz table, and the plate was moved manually per well. After the plasma treatment, cells were loaded with 150 μ l/well RPMI 1640 medium and incubated for the required hours.

3.5 Coculture with keratinocytes & fibroblasts

Direct coculture of HaCaT and GM Fbs was set up for cell migration assays and metabolic assays, as illustrated in figure 3.2. For coculture set up, GM Fbs were seeded first into a 96 well plate, and once they adhered to the plate, depending on the experimental type, the indicated number of HaCaT cells were seeded on top of GM Fbs. The exact cell numbers are described in the respective methods section.

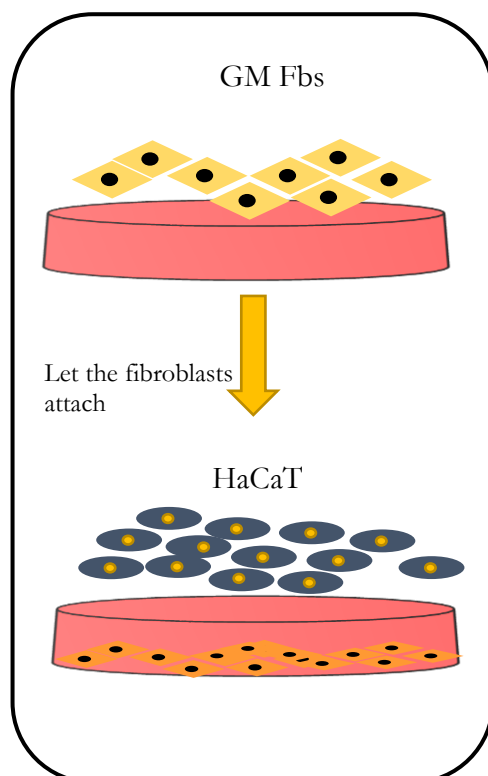

Figure 3.2 Coculture set up of HaCaT cells and GM Fbs. GM Fbs are seeded on the bottom, following which HaCaT cells are seeded on the top.

3.6 Harvest of GM Fbs conditioned medium

In a 24 well plate, 0.1×10^6 GM Fbs were seeded per well in complete RPMI medium, supplemented with 10% FCS. The cells were grown till 80-85% confluence after which the medium was replaced with 1% FCS containing RPMI medium. The cells were incubated in starving medium for another 16-18 hours. Next, fibroblasts were incubated with untreated or CAP treated medium (10, 30s) for another 18 hours. Following the incubation, conditioned medium was harvested, centrifuged for 5 min at 2000 rpm, filtered through a $0.22 \mu\text{m}$ syringe filter and stored at -80°C until further use.

3.7 Metabolic Activity assay

2.1×10^4 cells (in monoculture of HaCaT or GM Fbs) were seeded on a 96 well plate (Sarstedt) 24 hours before the experiment. For coculture, 0.7×10^4 GM Fbs were seeded first, followed by 1.4×10^4 HaCaT cells. Cells either in monoculture or coculture were incubated with untreated or CAP treated medium for 3 and 24 hours. As positive control, cells were treated with 10-30 μM H_2O_2 . After the mentioned incubation hours, wells were loaded with 100 μM of resazurin (Alfa Aesar) that is transformed to fluorescent resorufin by metabolically active cells. The plate was incubated at 37°C for 2 hours and the fluorescence was measured at λ_{ex} 535 nm and λ_{em} 590 nm using a Tecan plate reader. CAP and H_2O_2 treated fluorescence values were normalized against untreated control.

3.8 Intracellular ROS production with H_2DCFDA assay

Changes of intracellular redox levels were determined using $\text{H}_2\text{DCF-DA}$. 15000 cells were seeded into a 96 well plate and cultured at cell culture conditions for 24 hours. Afterwards, cells were stained with 1 μM of dye for 20 min, prior to plasma-treated medium was added, and the conversion from DCFDA to DCF was measured 10 minutes thereafter by reading the plate at λ_{ex} 485 nm and λ_{em} 530 nm.

3.9 Amplex Red Assay for H_2O_2 measurement

The concentration of hydrogen peroxide was determined by reaction of H_2O_2 with amplex red in the presence of HRP (Horse Radish Peroxide) that leads to the production of resorufin, a fluorescence active product. Amplex Red/HRP reagent consists in 100 μM of Amplex Red and 0.25 U/mL HRP in double ionized water. Since the higher concentration of H_2O_2 , able to be processed properly by this reagent is around 10 μM of H_2O_2 , plasma-treated medium was diluted 10 times previously to the addition of the reagent. 50 μL of the Amplex Red/HRP reagent was added to 200 μL of the 10-fold diluted plasma treated medium in a 96-well plate and incubated for 30 min at 37°C . Subsequent fluorescence measurements were performed by Tecan reader at λ_{ex} 560 nm and λ_{em} 590nm.

3.10 Cell migration assay

The cell migratory behavior of HaCaT cells and GM Fbs was assayed by a cell migration assay using Essen Bioscience wound maker. For this assay, monoculture of HaCaT, GM Fbs, and coculture of HaCaT and GM Fbs were used. For the mono culture, 6×10^4 HaCaT

3. Methods

cells/well and GM Fbs/ well were seeded in an Essen Bioscience 96 well Image lock plates. For the co-culture, 2×10^4 GM Fbs/well were seeded into image lock plates and incubated until the fibroblasts attach to the plates, and then 4×10^4 HaCaT cells/well were seeded onto the top of the fibroblasts at a ratio of 1:2 fibroblasts: keratinocytes within the coculture. A ratio of 1:3 and 1:5 fibroblasts: keratinocytes were also tested for the cell migration assay. Finally, for further experiments a ratio of 1:2 GM Fbs: HaCaT cells were used. After complete adherence of HaCaT cells, GM Fbs and coculture, the cells were starved to 1% FCS 16-18 hours prior to the experiment. Just prior to make the scratches, the old medium was replaced with 100 μ l of new RPMI medium. Essen Bioscience wound maker was used to make the scratches, afterwards cells were incubated with either 10 or 30 s plasma treated medium or untreated medium as indicated. For direct plasma treatment, after making the scratches 50 μ l of medium was taken out, plasma treatment was carried out and the medium was replaced with 150 μ l new medium.

For other experiments, recombinant CTGF (10-50 ng/ml) and Cyr61 (0.1-1 μ g/ml) and GM-Fb-conditioned media were used on HaCaT mono culture seeded at a density of 4×10^4 cells/well.

The migration rate was monitored with Incucyte S3 live cell analysis system until 24 hours. The relative wound density was measured with the in-built software of Incucyte S3 2018A. The relative wound density (%) is the ratio of the occupied area of the initially scratched area with respect to the total scratched area. The graphs are plotted as a function of relative wound density (%) in y-axis with respect to time at x-axis. The migration assay set up is shown in figure 3.3.

3. Methods

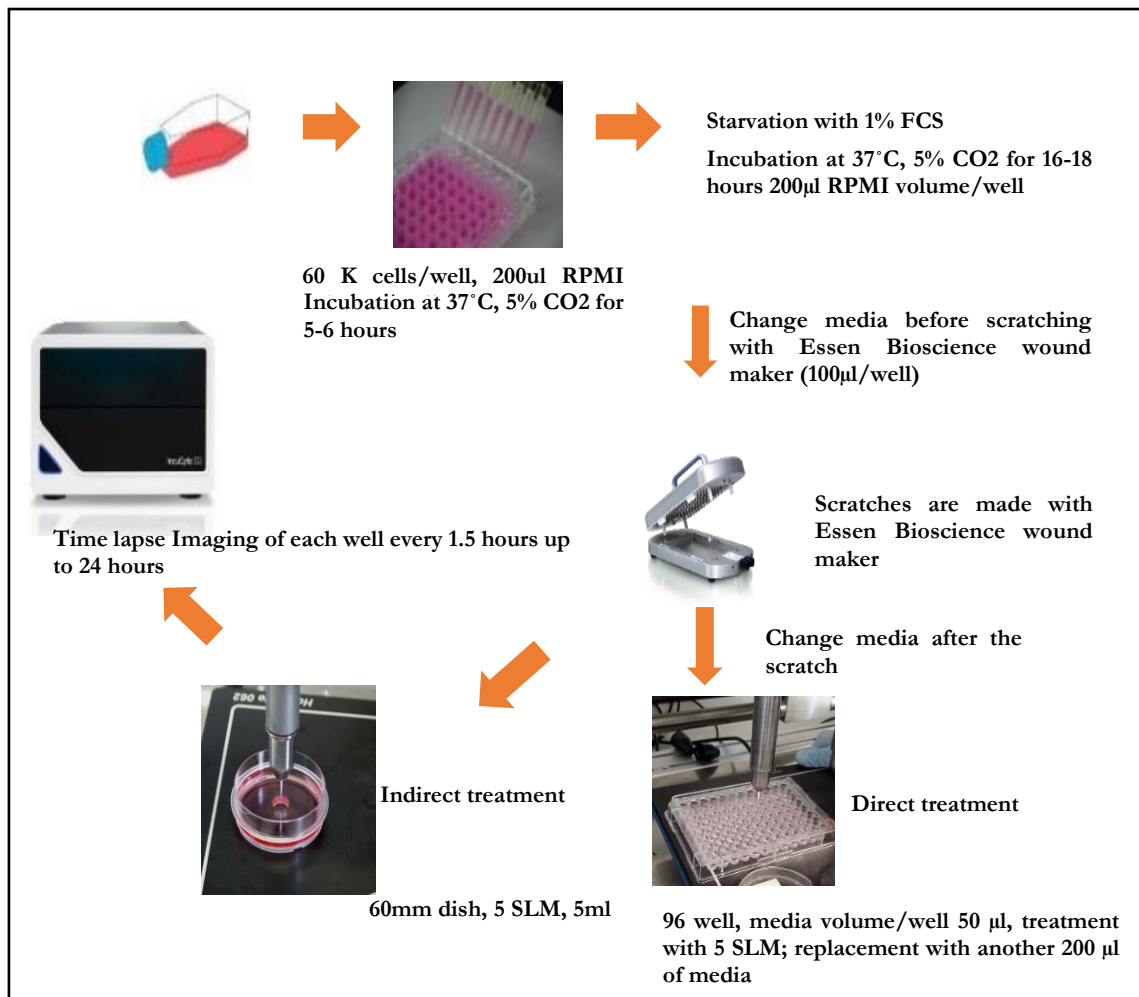

Figure 3.3 Cell migration assay set up

3.11 Gene expression analysis

3.11.1 RNA isolation

0.5×10^6 HaCaT cells or GM Fbs were seeded into a 6 well plate, and once the monocultures reached confluence, the cells were starved for 16-18 hours, scratches were made using a 10µl pipette tip and the cells were subsequently incubated with CAP treated medium or untreated control medium for indicated incubation hours. After that, the cells were washed with 1ml of ice-cold PBS and total RNA was isolated with RNA mini kit (Bio & Sell, Germany). Briefly, after washing with PBS, 400 µl of lysis buffer was added to the cells and either kept at -20°C for later processing or immediately processed with the following steps. Cell lysates were transferred to the blue column and centrifuged at $10,000 \times g$ for 2 minutes. The filtrate was then transferred to the purple column and mixed with equal volume (400 µl) of 70% ethanol and centrifuged again at $10,000 \times g$ for 2 minutes. The supernatant was discarded and 500 µl of wash buffer IT was added into the purple columns and

3. Methods

centrifuged at $10,000 \times g$ for 1 minute. The filtrate was discarded and second wash step was carried out with 700 μl of wash buffer MT and subsequently centrifuged at $10,000 \times g$ for 1 minute. Afterwards, the filtrate was removed and the columns were centrifuged at $10,000 \times g$ for 3 minutes to discard any residual wash buffer. Finally, elution was carried out with 40 μl of nuclease free water by centrifuging at $6000 \times g$ for 2 minutes. The RNA was then quantified with a spectrophotometer (Nanodrop 2000C, Thermo Fisher Scientific) and stored at -20°C for future use.

3.11.2 cDNA transcription

cDNA was synthesized with High-Capacity cDNA Reverse Transcription Kit (Thermo Fisher Scientific) according to manufacturer's protocol. Briefly, a master mix per sample was prepared as mentioned in table 3.1.

Table 3.1 Composition of transcription master mix per sample

Component	Volume
10X RT Buffer	2 μl
100mM dNTP mix	0.8 μl
10X random primers	2 μl
Multiscribe TM Reverse Transcriptase	1 μl
Nuclease free H ₂ O	4.2 μl
Total per reaction	10 μl

10 μl of master mix was admixed with 1 μg of RNA to a final volume of 20 μl and centrifuged shortly to spin down the contents and eliminate any residual air bubbles. Samples were incubated in a thermocycler using the conditions mentioned in table 3.2-

Table 3.2 Thermal cycling conditions

Settings	Step 1	Step 2	Step 3	Step 4
Temp	25°C	37°C	85°C	4°C
Time	10 min	120 min	5 min	∞

3.11.3 Quantitative Polymerase Chain Reaction

Gene expression was analyzed with Fast Start Essential DNA Green Master Mix (Roche). All the steps were carried out on ice. Thawed cDNA samples were diluted 1:10 with nuclease free water and qPCR mix for one reaction was prepared as summarized in the table 3.3.

3. Methods

Table 3.3 Composition of qPCR master mix

Reagent	Volume
2X SYBR Green Master Mix	5 μ l
PCR primers	2 μ l
Nuclease free water	13 μ l
Total volume	20 μ l

20 μ l PCR mix was pipetted into each well of the PCR plate and 1 μ l of cDNA template was added in each well. Subsequently, the multiwall plate was sealed with sealing foil (Sarstedt), centrifuged at $500 \times g$ for 2 minutes and immediately transferred in the LightCycler 480 instrument (Roche). qPCR program was started with the conditions mentioned in table 3.4.

Specific primer sequences (BioTez Berlin GmbH), analyzed in this thesis are mentioned in table 3.5. The house keeping gene β -actin was used as an internal control. Each sample was measured in technical triplicates and the gene expression analysis was performed with the $\Delta\Delta$ Ct method [179]. The final fold change in gene expression upon plasma treatment was determined according to the ratio of expression in the respective sample corresponding to the control.

3.11.4 RT² PCR Profiler Array

The gene expression profile of GM Fbs after CAP treatment was analyzed by Qiagen RT² PCR array. The RNA was isolated as described before and the cDNA was synthesized with the RT² first strand kit (Qiagen). For cDNA synthesis by RT² first strand kit, a gDNA elimination mix was prepared with 2 μ l of GE Buffer and 0.5 μ g of RNA to a total volume of 10 μ l. This mixture was incubated at 42°C for 5 minutes and immediately kept on ice afterwards for at least 1 minute. Subsequently, 10 μ l of reverse transcriptase mix was prepared per reaction consisting 4 μ l of BC3 buffer, 1 μ l of Control P2, 2 μ l of RT mix and 3 μ l of nuclease free water. This reverse transcriptase mix was then added with gDNA elimination mix and incubated at 42°C for 15 minutes followed by 95°C for 5 minutes in a thermocycler. Afterwards, 91 μ l of nuclease free water was added into each reaction and the cDNA was measured by a nanodrop. The cDNA was stored at -20°C for future use or proceeded directly with the qPCR array.

The qPCR array was performed with RT² ProfilerTM PCR Array Human Extracellular Matrix & Adhesion Molecules (PAHS-013ZF-6) and RT² ProfilerTM PCR Array Human Hippo Signaling (PAHS-172ZF-6). For one cDNA reaction, one 96 well plate was used. These 96 well plates were pre-coated with forward and reverse primer sequences of one gene. Besides housekeeping genes, 84 different genes were analyzed per array. A master mix of 1350 μ l of SyBr Green, 1248 μ l of nuclease free water and 102 μ l of cDNA was prepared; 25 μ l of this master mix was therefore aliquoted into each well of one 96 well plate. The plate was then centrifuged at 500g for 1 minute and the qPCR was carried out with Quantstudio 1 (Thermo Fisher Scientific) according to the protocol mentioned in table 3.6. Melting curve analysis was also performed to check the reactivity and specificity of the primer sequences. Data analysis was performed with the online free platform Gene Globe (Qiagen). A fold regulation greater than 2 (up or down) compared to the untreated control sample was

3. Methods

considered significant. The entire gene lists are mentioned in the appendix.

3.12 Protein expression analysis

3.12.1 Immunoblotting

HaCaT cells and GM Fbs were seeded at a density of 0.5×10^6 cells in a 6 well plate. After the cells reached confluence, they were serum starved for 16-18 hours, scratches were created using a 10 μ l pipette tip and the cells were subsequently incubated with CAP treated medium or untreated medium. Cells were washed with 1ml of ice-cold PBS and subsequently lysed with 100 μ l of RIPA buffer (composition in the table 3.7 below). Afterwards, this lysate was kept on ice for 20 min, followed by sonication step for 10 seconds per sample in ice. Next, the cell lysate was centrifuged at 15,000g at 4°C for 10 minutes. Supernatants containing the cellular proteins were transferred to another 1.5ml vial and total protein quantification was carried out using DCTM protein assay (BioRad).

3. Methods

Table 3.7 Composition of RIPA Buffer

Reagent	Concentration
PBS (without Ca ⁺² ,Mg ⁺²)	1X
Igepal CA -630 substance	1%
Sodium deoxycholate	0.5%
SDS	0.1%
EDTA	20mM

One tablet each of protease and phosphatase inhibitors (Sigma Aldrich) and 2mM of PMSF (Phenyl Methane Sulfonyl Fluoride, Carl Roth) was added in a freshly prepared 10ml RIPA buffer. This was then used as the RIPA lysis buffer.

25 µg of total protein concentration / per sample was then denatured at 95°C for 7 minutes using lysis buffer (composition summarized below in table 3.8) and proteins were resolved using a 10% precast SDS page gel (BioRad) in 1X running buffer, while a constant voltage of 125V was applied. 5 µl of pre-stained protein ladder was subjected to each gel. Composition of 10X running buffer is also summarized below in table 3.9.

Table 3.8 Composition of sample lysis buffer

Reagent	Concentration
Tris (Sigma Aldrich)	0.25M, pH 6.8
SDS	2%
Glycerol (Carl Roth)	10%
β-mercaptoethanol	2%
Bromophenol Blue (BPB)	0.004%

3. Methods

The proteins were thereafter transferred and blotted on a PVDF membrane with Trans blot Turbo™ for 7 min at 25V. The membranes were blocked with 2.5% BSA in TBST (Tris Buffered Saline Tween 20, table 3.10) for 1 hour. Subsequently, the membranes were incubated with primary antibodies (table 3.11) at a dilution of 1:1000 in TBST for overnight at 4°C. Next day, the membranes were washed with TBST thrice (10 min washing step each) which was followed by incubation with HRP conjugated secondary antibody (table 3.12, dilution 1:5000 in TBST) for 1 hour at room temperature. Bands were detected with chemiluminescence substrate (Thermo Fisher Scientific, Supersignal™ Femto Substrate) using Image Las 4000 (GE Healthcare). The band intensities were quantified with Image Studio Lite (version 5.2), normalized to housekeeping β -actin, and expressed as a fold change compared to corresponding untreated control.

3.12.2 Enzyme linked immunosorbent assay (ELISA)

Secreted proteins (CTGF and Cyr61) in cell culture conditioned media were analyzed by ELISA (table 3.13). Different providers were used and the experiments were performed according to manufacturer's protocol. Here only a general method is overviewed. 96 well plates, pre-coated with capture antibodies were brought to room temperature. Lyophilized standard was reconstituted with assay diluent and serial dilutions were performed to prepare the standard curve. Fibroblast conditioned media was directly added into the wells. About 100 μ l of each standard and samples were added into each well in at least duplicates. The wells were covered and incubated for 2-2.5 hour in room temperature. Following which, the samples and standards were discarded and the wells were washed 3-4 times with 1X wash buffer. After each wash, the plates were inverted and blotted against a clean paper towel. 100 μ l of protein specific biotinylated detection antibody was added in the wells and incubated for 1-2 hours with gentle shaking. Afterwards, the washing step was again performed 3-4 times. Next, 100 μ l of newly prepared HRP conjugated streptavidin solution was added to the wells and incubated for 45min-1 hour with gentle shaking. Subsequently, the solutions were discarded and the washing step was repeated. 100 μ l of substrate solution (TMB) was added to the wells and incubated for 30 min in room temperature in dark. Positive samples were now colored in blue. Reaction was stopped with 50 μ l of stop solution to each well, for which the color changed from blue to yellow. The absorbance was measured with a multimode plate reader (Tecan M200 pro) at 450nm and the reference was set at 570nm.

3.13 Immunofluorescence

Wounded monolayers of HaCaT cells and GM Fbs were incubated with untreated or CAP treated medium for 3 hours. Next, these monolayers were fixed in 4% paraformaldehyde diluted in PBS for 15 minutes. The samples were thereafter rinsed with 1X PBS for 3 times, 5 minutes each wash. The cells were permeabilized with PBS containing 0.3% Triton X-100 for 10 minutes, rinsed with PBS (3 times) and blocked with blocking buffer (1% BSA, 0.1% Tween 20 in 1X PBS) for 1 hour at room temperature. Next, the samples were incubated with mouse anti YAP (1:500, diluted in 1% BSA, 0.1% Tween 20 in 1X PBS,

3. Methods

Santa Cruz Biotechnology, sc-101199) for 1 hour at room temperature. Afterwards, the diluted primary antibody mix was decanted. Anti-mouse IgG (Alexa-Fluor 488, CST 4408S) was diluted 1:2000 in 1% BSA/PBST for 1 hour at room temperature in the dark. Secondary antibody was decanted and the cells were washed with 1X PBS for 3 time, 5 minutes each. Finally, the cells were incubated with 0.2 $\mu\text{g/ml}$ DAPI in PBS for 10 minutes in dark and imaged using an Axio Observer Z1 (Zeiss, Germany).

3.14 Statistics

Graphics and statistics were performed using prism 8.02 (GraphPad PRISM software, San Diego, USA). Mean and standard deviation were calculated and analyzed according to unpaired t-test with Welch's correction and ordinary one-way or two-way analysis of variance (ANOVA). A p value < 0.05 was considered statistically significant (* $p \leq 0:05$, ** $p \leq 0:01$, *** $p \leq 0:001$, and **** $p \leq 0:0001$).

4. Results

4.1 Characterization of H₂O₂ production in CAP treated medium

In majority of our experiments, CAP treated RPMI was used as medium (indirect treatment). Previous studies indicate, that amongst the short- and long- lived species produced by kINPen MED at 5 SLM, H₂O₂ is one of the most stable oxidants [180]. Therefore, we quantified the H₂O₂ concentration by the amplex red assay as described in the methods section. We observed a linear increase of the H₂O₂ concentration with treatment time (figure 4.1). 60s, the highest treatment time generated about 13 μ M of H₂O₂.

Figure 4.1 CAP generated hydrogen peroxide production in RPMI medium. Concentration of H₂O₂ after 10, 30 and 60s of plasma treatment with kINPen MED operated at 5 SLM with argon flux. No plasma treatment served as the negative control. Data are presented as mean \pm S.D. from two independent experiments. Statistical comparisons are performed using one-way ANOVA.

4.2 Intracellular ROS production in HaCaT and GM Fbs

2',7' -dichlorofluorescein diacetate is a cell permeable dye, which is first deacetylated by cellular esterases but later oxidized by ROS into 2', 7' -dichlorofluorescein, a highly

4. Results

fluorescent compound. We already demonstrated that CAP treatment produces H_2O_2 in RPMI medium. Therefore, we performed the H_2DCFDA assay. We observed an increase in intracellular ROS production in both HaCaT and GM Fbs (figure 4.2). To be precise, compared to untreated negative control, ROS production was 1.2-fold higher in HaCaT cells and 1.3-fold higher in GM Fbs with the highest plasma treatment of 60s. 100 μM of H_2O_2 served as a positive control, which showed a significant induction of intracellular ROS in both the cell lines.

Figure 4.2 Effect of CAP on intracellular ROS levels. Intracellular ROS production was measured by 2, 7'-dichlorofluorescein (DCF) fluorescence in (A) HaCaT cells and (B) GM Fbs. Data are presented as mean \pm S.D. from two independent experiments, each performed in technical quadruplets. Statistical comparisons were performed using one-way ANOVA.

4.3 Influence of CAP on metabolic activity in mono and coculture

4.3.1 Metabolic activity of mono and coculture after 3 and 24 hours of CAP treatment

The Alamar Blue assay measures the cell viability of metabolically active cells. Alamar Blue assay serves as the redox indicator of cells, is cell permeable, non-toxic and acts as an intermediate electron acceptor in the electron transport chain without interference of the normal transfer of electrons. This is in direct correlation to the NADPH content of cells which further refers to the cells capability to generate ATP. Hence, constant monitoring of cells in culture is possible by Alamar Blue assay.

We performed the Alamar Blue assay with the monocultures HaCaT, GM Fbs and the coculture (figure 4.3). 10 and 30 s CAP treatment did not significantly alter the metabolic activity of HaCaT, GM Fbs and coculture after 3 hours of treatment. However, 60s treatment

4. Results

could lead to a significant reduction of metabolic activity in all the cell types. 24 hours after the CAP treatment, HaCaT cells and the coculture did not show a further reduction in cell viability, however, in GM Fbs, both 30s and 60s treatment significantly reduced cell viability. Based on these results, we excluded 60s treatment for most of our subsequent experiments.

Figure 4.3 Influence of CAP on metabolic activity of mono and coculture. The metabolic activity of HaCaT cells, GM Fbs, and coculture after 3 h in response to 10, 30, and 60s of CAP treatments. Untreated RPMI served as control (A). Metabolic activity of the same cell types after 24 h of CAP treatment (B). Data are presented as mean \pm SD of three independent experiments performed in triplicate. Statistical comparisons were performed using one-way ANOVA.

4.3.2 Influence of NAC on metabolic activity in mono and coculture

NAC or N-acetyl L-cysteine is a precursor of L cysteine, a potent antioxidant and acts directly as a scavenger of free radicals especially oxygen radicals. To determine the effect of CAP produced ROS on metabolic activity, cells were incubated with 2.5 mM NAC alone or in combination with 10, 30 and 60 s CAP treated medium for 3 and 24 hours. 60 μ M H_2O_2 alone or in combination with NAC was used as a positive control. As observed in figure 4.4, NAC alone did not significantly increase the metabolic activity in HaCaT and

4. Results

coculture in 3 hours. However, in GM Fbs, there was a significant increase in metabolic activity when cells were treated with NAC alone. In all the three cell types, NAC treatment in combination with cold plasma restored the metabolic activity within 3 hours. In fact, a significant increase in metabolic activity was observed in both GM Fbs and coculture when NAC was incubated with 60s plasma treated medium. As expected, the positive control H_2O_2 decreased the metabolic activity in all the three cell types, but NAC restored the metabolic activity when treated in combination with H_2O_2 . These proves that NAC is able to act as a scavenger in this experimental set up. Due to its antioxidant activity, metabolic activity was restored already after 3 hours of incubation with plasma-treated medium.

Figure 4.4 Effect of NAC on metabolic activity after 3 h of CAP treatment. Metabolic activity of HaCaT cells, GM Fbs, and coculture after 3 h incubation with 2.5mM NAC alone or in combination with CAP-treated media. Data are presented as mean \pm SD from at least three independent experiments performed in triplicate. Statistical analysis was performed using one-way ANOVA.

As observed in figure 4.5, after 24 hours, NAC alone did not significantly alter the metabolic activity in HaCaT cells and coculture. However, metabolic activity was increased in GM Fbs upon incubation with NAC alone. In HaCaT cells, 60s plasma treatment and 60 μ M H_2O_2 significantly reduced the metabolic activity in HaCaT cells. But, NAC counteracted plasma and H_2O_2 treatment and restored the metabolic activity. In GM Fbs, as observed before, incubation with plasma treated medium and 60 μ M H_2O_2 significantly reduced the metabolic activity. But, NAC counteracted 10, 30, 60 s CAP treatments and H_2O_2 and hence increased the metabolic activity. In coculture, NAC significantly counteracted the effects of 30s of CAP treatment and increased the metabolic activity of these cells.

4. Results

Figure 4.5 Effect of NAC on metabolic activity of CAP treated cells after 24 h. Metabolic activity of HaCaT cells, GM Fbs, and coculture after 24 h incubation with 2.5mM NAC alone or in combination with CAP-treated media. Data are presented as mean \pm SD from at least three independent experiments performed in triplicate. Statistical analysis was performed using one-way ANOVA.

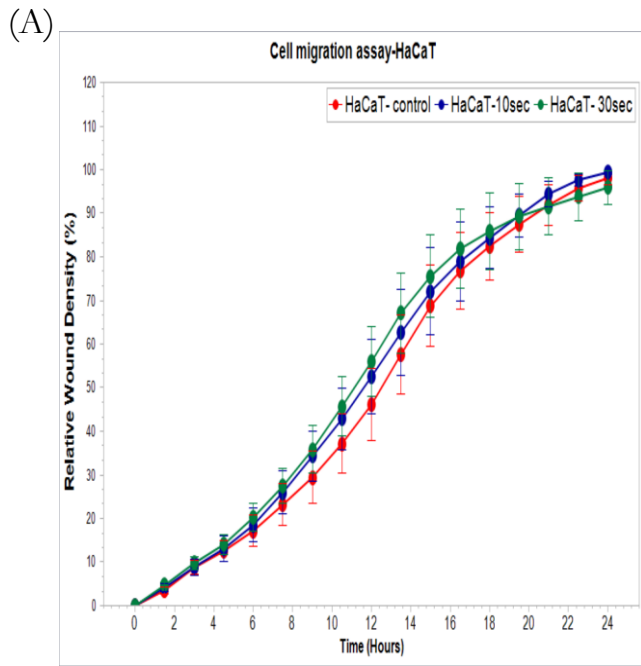

4.4 Influence of CAP on cell migration in mono and coculture

One of the most important steps in wound closure is the ability of cells to migrate in the wound bed. The proliferative stage of wound healing is primarily dominated by proliferation and cell migration of dermal keratinocytes and dermal fibroblasts. To exclusively monitor cell migration, we starved the cells for 18-20 hours prior to the experiment. In fact, during the entire process of cell migration assay, only 1% FCS was used. Cell migration was monitored upon indirect and direct plasma treatment as mentioned in the methods section.

4.4.1 Influence of indirect CAP treatment on cell migration

60k cells/ well either in monoculture or in coculture (40K HaCaT, 20K GM Fbs), after making scratches by wound maker, were incubated with 200 μ l of untreated or 10-30s CAP treated media until 24 hours. Figure 4.6 and figure 4.7 illustrates that, indirect CAP treatment (10s, 30s) did not significantly modify the relative wound density in HaCaT or GM Fbs. In fact, 30s treatment showed a minor delay in migration in GM Fbs. However, in case of coculture (figure 4.8), CAP treatment could significantly accelerate the relative wound density from 12 hours. This result indicates that the CAP treatment could have a significantly different effect on monocultures and coculture.

Statistical comparisons were performed using two-way ANOVA.

4. Results

We also compared the relative wound density between HaCaT cells alone and those cocultured with fibroblasts (figure 4.9), and we observed that, 10s indirect CAP treatment could significantly accelerate relative wound density in coculture compared to HaCaT monoculture alone. 30s CAP treatment also showed similar results where a significant increase in relative wound density in coculture was observed at 12 hours. These results further indicate that, CAP mediated cell migration varies depending on cell type and dermal cell interactions could also significantly alter CAP-mediated cell migratory effect.

Figure 4.9 Comparison of relative wound density between untreated and CAP-treated HaCaT cells and coculture. (A), (B) and (C) details the comparative analysis of cell migration between HaCaT mono culture and co culture after incubation with untreated, 10s and 30s CAP treated medium at 6, 12, 18 and 24 h. Data are presented as mean \pm SD from three independent experiments. Statistical comparisons are performed with two-way ANOVA.

4.4.2 Influence of NAC on cell migration of HaCaT and coculture

HaCaT cells and coculture were incubated with 2.5 mM NAC alone or in combination with CAP treated medium in cell migration assays for 24 hours. Interestingly, we observed that NAC alone did not improve HaCaT cell migration. Upon, CAP treatment, no significant acceleration in relative wound density of HaCaT cells were observed (like figure 4.6). But, upon NAC administration with CAP treated medium, relative wound density of HaCaT cells was reduced as observed in figure 4.10.

In coculture, similar results were obtained, as demonstrated in figure 4.11. Starting from 12 hours, NAC treatment reduced CAP-induced acceleration of relative wound density. At later time point (24 hours), treatment with NAC alone significantly reduced relative wound

4. Results

density compared to control. NAC reduced CAP mediated cell migration to ~40-50% at later hours (starting from 18 hours) in coculture.

Figure 4.10 Effect of NAC on HaCaT cell migration. (A) details the relative wound density of HaCaT cells after treatment with NAC alone or in combination with CAP-treated media at 6, 12, 18, and 24 h. Data are presented as mean \pm SD of three independent experiments performed in triplicate. Statistical comparisons were performed using two-way ANOVA.

4. Results

Figure 4.11 Effect of NAC on coculture cell migration. (A) details the relative wound density of coculture after treatment with NAC alone or in combination with CAP-treated media at 6, 12, 18, and 24 h. (B) depicts the representative time course of wound closure in coculture treated with CAP alone or in combination with 2.5mM NAC. Data are presented as mean \pm SD of three independent experiments performed in triplicate. Statistical comparisons were performed using two-way ANOVA.

4.4.3 Influence of direct CAP treatment on cell migration

HaCaT cells in monoculture or cocultured with fibroblasts were also directly treated with 5 SLM plasma for 10 and 30s with kINPen MED (as mentioned in the methods section) and we analyzed the effect of direct CAP treatment on cell migratory behavior. EGF (10ng/ml) was used as a positive control for cell migration. Figure 4.12 illustrates that direct CAP treatment (both 10 and 30s) did not accelerate relative wound density in HaCaT cells. In fact, both 10 and 30s of direct treatment showed a tentative reduction in relative wound density compared to control starting from 12 hours. However, on the contrary, in coculture, 10s direct CAP treatment accelerated relative wound density compared to control starting from 12 hours. But, 30s direct CAP treatment could not improve the relative wound density. This could be due to long- and short- lived species produced by 30s direct CAP treatment, which could already start to exert an oxidative stress on cells resulting in delayed cell migration. As 10s direct CAP treatment stimulated cell migration in HaCaT cells cocultured with fibroblasts, an effect of CAP on cell-cell interaction during wound healing is indicated.

Figure 4.12 Influence of direct CAP treatment on cell migration in HaCaT and coculture. (A) and (B) depicts the summation of relative wound density in HaCaT monoculture and coculture upon untreated, 10 and 30s direct CAP treatment at specific time points 6, 12, 18 and 24 h. EGF (10ng/ml) served as the positive control. Data is presented as mean \pm SD from two independent experiments, each with triplicates. Statistical comparisons were performed with two-way ANOVA.

4. Results

We compared the effect of direct CAP treatment and CAP-treated medium (indirect treatment) on cell migration in figure 4.13. We observed that compared to control and direct CAP treatment, indirect CAP treatment (30s) could significantly accelerate relative wound density in coculture (figure 4.13). In HaCaT cells, there was a tendency of improved cell migration upon 10s indirect CAP treatment compared to direct CAP treatment, but it was not significant. In fact, as shown in figure 4.13 (C, D), compared to control, relative wound density (%) was reduced upon direct CAP treatment in HaCaT cells. The wound closure was faster in response to indirect CAP treatment in mono and coculture compared to direct CAP treatment, therefore, we used indirect CAP treatment for the rest of the thesis.

Figure 4.13 Comparison of direct and indirect CAP treatment in HaCaT cells and coculture. (A) and (B) depicts the comparison of relative wound density between direct and indirect CAP treatment in coculture at 6, 12, 18 and 24 h. (C) and (D) details the comparison of relative wound density between direct and indirect CAP treatment in HaCaT cells at 6, 12, 18 and 24 h. Data are presented as mean \pm SD from two independent experiments, each in triplicates. Statistical comparison is performed with two-way ANOVA.

4.5 CAP activates HIPPO signaling axis

We observed that cells in coculture closely mimics skin due to inclusion of both keratinocytes and fibroblasts and exhibited an improved CAP stimulation effect compared to those observed in monocultures, indicating a crosstalk between plasma treated cell types. To more thoroughly assess the paracrine signaling between the two cell types, we examined the signaling pathways involved in tissue homeostasis and regeneration. Emerging evidence suggests the activation of HIPPO signaling pathway in response to mechanical stress, cellular stress and oxidative stress [104]. Hence, we were interested to investigate this signaling axis in response to CAP treatment in HaCaT cells and GM Fbs, as it plays an important role in cell growth, proliferation, and tissue homeostasis and is under redox control. [104]

4.5.1 CAP activates YAP-CTGF-Cyr61 signaling pathway

HaCaT and GM Fbs were incubated with untreated or 10 and 30s CAP treated medium (indirect treatment) for 3, 6, 18 and 24 hours. Quantitative PCR analysis showed that (figure 4.14), compared to early time point (3 hours), 30s CAP treatment could lead to a two-fold upregulation of YAP mRNA expression after 6 hours in GM Fbs. CTGF and Cyr61, downstream of YAP was also upregulated upon CAP treatment. In fact, 30s CAP treatment led to an about four-fold upregulation in CTGF mRNA expression at around 18 hours, which declined to near baseline by 24 hours. Cyr61 gene expression was also significantly induced starting after 6 hours, which peaked to three-fold upregulation in 18 hours and then declined to baseline by 24 hours.

Figure 4.14 mRNA expression of HIPPO signaling effectors in GM Fbs after CAP treatment. Gene expression of YAP (A), CTGF (B) and Cyr61 (C) in GM Fbs measured 3, 6, 18, and 24 h after CAP treatment by qPCR and normalized to relative gene expression ($\Delta\Delta C_t$ values on a log 2 scale). The *x*-axis represents CAP treatment time and incubation time after plasma treatment. Data are represented as mean \pm SD of four independent experiments. Statistical analysis was performed using unpaired *t*-test with Welch's correction for multiple comparisons, along with normalization to the untreated control.

4. Results

Figure 4.15 depicts the gene expression of YAP, CTGF and Cyr61 in HaCaT cells. In contrast to GM Fbs, a significant upregulation of YAP mRNA expression in HaCaT cells was not observed at early hours. However, both 10 and 30s CAP treatment tends to upregulate YAP gene expression after 24 hours. In case of CTGF, minimal upregulation (~1.4 -fold) was observed at 3 and 18 hours. Cyr61 gene expression was also minimally induced at 3 hours (about 1.5-fold) in HaCaT cells

Figure 4.15 mRNA expression of HIPPO signaling effectors in HaCaT cells. Gene expression of YAP (A), CTGF (B) and Cyr61 (C) in HaCaT cells measured 3, 6, 18, and 24 h after CAP treatment by qPCR and normalized to relative gene expression ($\Delta\Delta C_t$ values on a log 2 scale). The x-axis represents CAP treatment time and incubation time after plasma treatment. Data are represented as mean \pm SD of three independent experiments. Statistical analysis was performed using unpaired t-test with Welch's correction for multiple comparisons, along with normalization to the untreated control.

The protein expression level of these signaling molecules were also checked after 3, 6 and 24 hours of plasma treatment (figure 4.16, 4.17). As mentioned before, unphosphorylated YAP moves to the nucleus, binds to TEAD transcription cofactors and transcribes the downstream genes namely CTGF and Cyr61. Therefore, the phosphorylation status of YAP was checked in both GM Fbs and HaCaT cells. Under serum starved conditions, as shown in figure 4.16, the ratio of phosphorylated YAP compared to total YAP was not significantly altered in GM Fbs. However, unlike the fibroblasts, there was a tendency of increased expression of phosphorylated YAP in HaCaT cells.

4. Results

Figure 4.16 Effect of CAP on YAP protein expression. The relative phosphorylation level of YAP is shown in GM Fbs (A) and HaCaT cells (B). Quantification is performed from three independent blots. Representative blots are shown. The x-axis represents CAP treatment time and incubation time after plasma treatment. Data are represented as mean \pm SD of at least three independent experiments. Statistical analysis was performed using unpaired t-test with Welch's correction for multiple comparisons, along with normalization to the untreated control.

Next, we checked the CTGF and Cyr61 protein expression in both the cell lines. In GM Fbs, we observed an increase in total cellular CTGF (\sim 2-fold) in 3 hours and in total cellular Cyr61 (\sim 3-fold) after 3 hours and (\sim 2-fold) after 6 hours. In contrast to GM Fbs, HaCaT cells did not show any detectable range of cellular Cyr61. CTGF protein expression was also minimally increased (\sim 1.5-fold) in HaCaT cells.

4. Results

Figure 4.17 Effect of CAP on CTGF and Cyr61. CTGF and Cyr61 protein expression was enhanced after 10 and 30 s of CAP treatment in GM Fbs (A, B). CTGF expression slightly increased after 10 and 30 s of CAP treatments in HaCaT cells after approximately 3 h (C). Representative blots are shown. The *x*-axis represents CAP treatment time and incubation time after plasma treatment. Data are represented as mean \pm SD of at least three independent experiments. Statistical analysis was performed using unpaired *t*-test with Welch's correction for multiple comparisons, along with normalization to the untreated control.

4.5.2 Effect of CAP on other signaling molecules in cross talk with YAP

HaCaT and GM Fbs were incubated with untreated, 10 and 30s CAP treated medium for 3, 6, 12, 18 and 24 hours. Apart from the major signaling axis, we also investigated the gene expression upon CAP treatment in functional mediators which are in cross talk with HIPPO signaling pathway (figure 4.18). We checked the gene expression of mTOR in both the cell lines. A significant upregulation of mTOR (~ 2-fold) was observed in GM Fbs after 12 hours and ~1.5-fold in HaCaT cells after 24 hours.

HIF-1 α gene expression was also monitored upon CAP treatment. In GM Fbs, HIF-1 α seemed to be upregulated (~1.8-2.6 fold) upon CAP treatment around 6 hours, but it was not significant. HaCaT cells, around 24 hours, also showed an upregulation of HIF-1 α (~1.8-fold), but not significant. Both IGF-1 and IGF-2 gene expression was monitored in both the cell lines. CAP upregulated IGF-1 in GM Fbs around 24 hours to ~2.8-4 fold and ~2.2-fold in HaCaT cells. However, the differential expression of IGF-1 was not significant. IGF-2 upregulation was also not significant in both the cell lines.

Unlike the YAP-CTGF-Cyr61 axis, these molecules did not show a significant upregulation in their mRNA expression upon both the CAP treatments. Hence, for the following analysis of this signaling pathway, YAP, CTGF and Cyr61 were focused.

4. Results

Figure 4.18 Gene expression of signaling molecules in crosstalk with YAP. Gene expression of signaling molecules in GM Fbs (A,C) and HaCaT cells (B,D) measured 3, 6, 12, 18, and 24 h after CAP treatment by qPCR and normalized to relative gene expression ($\Delta\Delta C_t$ values on a log 2 scale). The x-axis represents CAP treatment time and incubation time after plasma treatment. Data are represented as mean \pm SD of two independent experiments. Statistical analysis was performed using one-way ANOVA, along with normalization to the untreated control.

4.5.3 Effect of CAP on nuclear translocation of YAP

YAP lacks a canonical nuclear localization signal and its nuclear accumulation machinery is not well understood. The transcriptional activity is majorly dependent on nuclear YAP, thus through nucleocytoplasmic shuttling the HIPPO pathway controls its temporal activity. As we could see an upregulation of CTGF and Cyr61 gene and protein expression upon CAP treatment, we quantified the presence of total YAP in nucleus and cytoplasm after 3 hours of CAP treatment.

Immunofluorescence staining was applied to visualize the total YAP content in nucleus and cytoplasm in untreated and plasma treated HaCaT and GM Fbs. A positive nuclear staining of YAP was detected in both the cell lines in control and CAP treated samples. Nuclear and cytoplasmic YAP intensity was calculated by Image J. Upon quantification, in HaCaT cells (figure 4.19), no significant difference in the ratio of nucleus: cytoplasmic YAP was observed. In fact, in both control and plasma treated samples, nuclear staining of YAP was higher compared to cytoplasm and N/C ratio of YAP was around ~5. In GM Fbs, as observed in figure 4.20, like HaCaT cells, both control and CAP treated GM Fbs showed nuclear accumulation of YAP. But interestingly, compared to untreated GM Fbs, 10s showed a significant drop in nuclear YAP accumulation. The N/C YAP ratio in control was around ~6, compared to an N/C ratio of ~5.2 in plasma treated samples.

Statistical analysis was performed with one-way ANOVA.

4.5.3 Effect of NAC on YAP-CTGF-Cyr61 signaling cascade

We have previously observed CAP mediated upregulation of HIPPO signaling cascade in GM Fbs. To exclusively conclude the role of stable CAP derived oxidants in YAP-CTGF-Cyr61 signaling cascade activation, 2.5mM NAC was incubated for 18 hours with untreated and CAP treated medium before RNA was isolated from the cells. As observed in figure 4.21, NAC alone did not have any significant impact on these HIPPO molecules in HaCaT cells. NAC in combination with 10 and 30 s CAP-treated media significantly reduced the expression of CTGF (~2.4-fold) and Cyr61 (~1.9-fold) in GM Fbs. YAP expression was slightly but not significantly reduced in GM Fbs.

Similar results were obtained in HaCaT cells that revealed that YAP expression remained unaltered upon treatment with NAC alone or in combination with plasma. CTGF expression was also reduced upon NAC treatment in HaCaT cells (but no significance). Cyr61 mRNA expression in HaCaT cells were significantly reduced upon NAC treatment in combination with both 10 and 30s CAP treatment. This study further signifies that, stable ROS produced from CAP significantly activates the YAP-CTGF-Cyr61 axis. In presence of ROS quencher NAC, this CAP mediated signaling cascade is terminated.

4. Results

(A)

(B)

Figure 4.21 Effect of NAC on the YAP-CTGF-Cyr61 signaling cascade. Gene expression of YAP, CTGF, and Cyr61 in GM Fbs (A) and HaCaT cells (B) measured 18 h after CAP treatment by qPCR and normalized to relative gene expression ($\Delta\Delta C_t$ values on a log 2 scale). Data are presented as mean \pm SD from at least three independent experiments, and statistical analysis was performed using unpaired t-test with Welch's correction.

4.5.4 CAP Promotes Migration in coculture through Secreted CTGF and Cyr61

In our coculture migration experiments (figure 4.8), we observed significantly higher acceleration in cell migration compared to HaCaT cells alone upon CAP treatment. Therefore, we hypothesized that CAP not only influences the keratinocytes and fibroblasts alone, but also regulates their interaction in a coculture. We assumed that the major signaling molecules activating this paracrine signaling are CTGF and Cyr61.

4. Results

Therefore, we first analyzed the GM Fb conditioned medium (collected 18 hours after CAP treatment) by ELISA and we observed an increase in secreted CTGF and Cyr61 upon CAP treatment (figure 4.22). Next, we performed a cell migration assay with recombinant CTGF and Cyr61. HaCaT monoculture was treated with 10 and 50 ng/ml of recombinant CTGF and 100 ng and 1 μ g/ml of Cyr61 (Peprotech GmbH). Treatment with both 10 and 50 ng/ml CTGF significantly accelerated cell migration (figure 4.23 a-b). Treatment with either 100 ng/ml or 1 μ g/ml Cyr61 also accelerated cell migration at early time point (figure 4.23 c-d).

Figure 4.22 CAP enhances secreted CTGF and Cyr61 expression from GM Fbs. Secreted CTGF (A) and Cyr61 (B) (pg/ml) was analyzed by ELISA. Data are presented as mean \pm SD from two independent experiments, and statistical analysis was performed using one-way ANOVA.

4. Results

Figure 4.23 Cell migration of HaCaT monoculture in presence of recombinant CTGF and Cyr61. Relative wound density in HaCaT cells was monitored after treatment with 10 and 50 ng/ml CTGF and 100 ng/ml and 1 µg/ml Cyr61. (A) Details the summation of relative wound density upon treatment with recombinant 10 and 50 ng/ml CTGF. (B) Details of a representative time course analysis of CTGF mediated wound healing in HaCaT cells. (C) Depicts the summation of relative wound density upon treatment with recombinant 100 ng/ml and 1 µg/ml Cyr61. (D) Details a representative time course analysis of Cyr61 mediated wound healing in HaCaT cells. Data are presented as mean ± SD from three independent experiments, and statistical analysis was performed using two-way ANOVA.

As we observed that recombinant CTGF and Cyr61 have the potential to stimulate cell migration of HaCaT monoculture, we assumed that the secreted CTGF and Cyr61 in GM Fbs CM would accelerate HaCaT wound healing. Therefore, we performed a cell migration assay to determine the migratory behavior of HaCaT cells grown in media conditioned from untreated or CAP-treated GM Fbs (figure 4.24). As expected, conditioned medium harvested from 10 and 30s CAP-treated GM Fbs at 18 hours significantly accelerated

4. Results

HaCaT cell migration compared to conditioned medium from untreated GM Fbs and normal medium (control).

Figure 4.24 Effect of CAP on paracrine signaling between keratinocytes and fibroblasts. HaCaT cells were incubated with conditioned media harvested from untreated or 10 and 30 s CAP-treated GM Fbs. Data are presented as mean \pm SD from three independent experiments, and statistical analysis was performed using two-way ANOVA.

4.6 Influence of CAP on regenerative signaling molecules

Our study validated the activation of a regenerative signaling axis in dermal cells and thus indicated the activation of a paracrine signaling pathway upon CAP treatment. We already observed the activation of YAP-CTGF-Cyr61 axis in GM Fbs, which in turn stimulates a reciprocal communication with HaCaT cells resulting in improved wound healing of keratinocytes, cocultured with the fibroblasts. To gain further insights on the regenerative

4. Results

signaling in GM Fbs, RT² PCR profiler array was performed 6 hours after 30 and 60s of CAP treatment. 84 genes from HIPPO signaling axis and 84 genes from extracellular matrix and adhesion molecules were investigated through the array.

4.6.1 CAP activates HIPPO signaling molecules in GM Fbs

GM Fbs were treated with untreated, 30s and 60s of CAP treatment after making scratches to figure out the differential gene expression upon CAP treatment in a wound healing set up. 84 genes of HIPPO signaling pathway was analyzed by RT² PCR array. These genes belong to different subgroups of biological process including metabolic process, biological adhesion, cellular component organization, biological regulation, signaling etc. The PANTHER classification of these genes according to biological process are listed in figure 4.25.

30s CAP treatment resulted in upregulation of 3 genes and 60s treatment could upregulate 59 genes compared to untreated control, 6 hours after treatment. As shown in table 4.1, both 30s and 60s CAP treatment induced FAT2 gene, transcribing cadherin family protein to 2.03-fold and 3.84-fold respectively. Another cadherin member gene transcribing DCHS1 was also upregulated by both 30 and 60s to 3.93 and 13.01-fold respectively, 6 hours after treatment. Cyclin family member genes Cyclin E1 and Cyclin E2 were also significantly upregulated by 60s of CAP treatment. LATS1 and LATS2 genes transcribing STK protein kinases, directly upstream of YAP transcription factor was also significantly upregulated > 4-fold within 6 hours of 60s treatment. Another cell adhesion and cell motility gene transcribing LIM1 was also significantly upregulated by CAP treatment. NF2, another gene involved in cytoskeletal dynamics was also upregulated >4-fold by 60s CAP treatment. Protein phosphatase family member genes PPP2CB, PPP2R1A and PPP2R1D were also upregulated (>2-fold) by 60s treatment. All the TEAD family member genes (1, 2, 3 and 4) were upregulated (>2-fold) within 6 hours of CAP treatment. Another transcriptional corepressor WTIP1 and transcriptional coactivator WWC1 were also significantly

4. Results

upregulated to more than 3-fold by 60s CAP treatment. YAP as previously shown before, was also upregulated >4-fold by 60s CAP treatment after 6 hours. Gene ontology analysis was carried out by DAVID. As demonstrated in figure 4.26, the functional annotation of genes showing significant enrichment ($p < 0.05$) compared to control were classified according to biological process, molecular function and cellular components.

30s CAP treatment increased Matrix Metallo Proteinases 3 (MMP3) expression and 60s CAP treatment resulted in differential regulation of 34 genes. 60s CAP treatment significantly increased the expression of genes transcribing collagen moieties including COL12, COL15, COL4, COL5, COL6 and COL7. ADAMTS, a family of multidomain extracellular protease enzymes, showed differential regulation upon CAP treatment. ADAMTS 1 and 13 were significantly upregulated upon 60s CAP treatment in 6 hours, whereas ADAMTS8 was downregulated. Integrin family genes ITGB 2 and 4 were also significantly upregulated upon 60s CAP treatment. MMPs showed a differential regulation upon 60s CAP treatment. MMP 3 and 14 were significantly upregulated whereas MMP8 and MMP12 were downregulated. Several genes transcribing cell adhesion molecules like CDH1, VCAM1 and PECAM1 were also downregulated. Genes transcribing extracellular matrix proteins like ECM1 and LAMB1 were significantly downregulated upon CAP treatment. Gene ontology analysis was carried out by DAVID. The functional annotation of upregulated and downregulated genes compared to control were classified according to biological process, molecular function and cellular components (figure 4.28, 4.29).

5. Discussion

The aim of this study was to examine the stimulatory effect of CAP on cell migratory behaviors and molecular signaling resulting in wound healing. For this, we performed cell migration experiments accompanied with gene and protein expression studies focusing on the HIPPO signaling pathway. The results show for the first time the activation of this pathway in dermal fibroblasts and paracrine regenerative signaling between keratinocytes and fibroblasts upon CAP treatment. The effect of CAP on cell migration of monoculture and coculture was also studied separately. This study also aimed to generate a regenerative signaling molecule map upon CAP treatment in a wound healing set up.

5.1 Effect of CAP on cell migration and extracellular matrix molecules

There are compelling evidences in previous studies that H_2O_2 is one of the stable oxidants produced by CAP. Wende et al. have previously shown that feed gas composition is an important contributor of plasma generated chemical entities [180]. H_2O_2 is an important second messenger generated by CAP which triggers the release of growth factors during the wound healing process and has been shown to increase keratinocyte viability and migration in wound models [181]. Therefore, the first focus of the thesis was to quantify H_2O_2 in RPMI. kINPen is primarily an argon plasma jet which in contact with ambient air and cell culture medium generate radical and non-radical species [151]. We quantified the H_2O_2 concentration in 5 ml RPMI medium after 10, 30 and 60s of plasma treatment with kINPen MED, and we observed a time dependent increase of H_2O_2 production (figure 4.1) as shown in previous studies.

The epidermal layer functions as a barrier to the outside of the skin, and upon damage, newly divided keratinocytes cover damaged skin by migrating across the dermis. Here, we optimized monocultures of HaCaT and GM Fbs and an *in vitro* coculture model that incorporated both keratinocytes and fibroblasts at a ratio of 2:1. Unlike in single cell studies, the coculture model for migration studies provides the opportunity to monitor the influence of the two cell types on each other after CAP treatment. We investigated the cell migration rate in a scratch wound assay. There are a few limitations of manual *in vitro* scratch assay. For example, manual scratch with pipettes could yield in higher variability in initial wound size and shape. Removed cells could also accumulate at the edge of wound sites [182]. In

5. Discussion

contrast, we executed scratches with the Essen Bioscience wound maker, as described in the methods section. With its identical 96 pins, the variability in wound size was reduced and higher reproducibility was achieved in experimental replicates. Upon a standardized scratch formation, monocultures and coculture were incubated with untreated and plasma-treated medium until 24 hours followed by a computerized analysis.

CAP did not significantly increase the cell migration rate in keratinocytes and fibroblasts (figure 4.6, 4.7). Previously Loo et al. has described that H_2O_2 , one of the long-living molecule produced by CAP, could stimulate migration of keratinocytes in a scratch wound model [183]. In our studies, for HaCaT cells, even though a tendency of increased migration rate for 10 and 30s starting from around 18 hours was observed, the difference was not significant. In the scratch wound model, GM Fbs did not migrate collectively, but rather they migrated as single cells. Depletion of NF2 reduces the collective motility in epithelial cells, but increases the individual cell motility [184]. CAP mediated upregulation of NF2 probably supports single cell motility in fibroblast monolayer. The cellular adhesion receptor CD44 was also upregulated upon cold plasma treatment. CD44 is important for facilitating an organized directional migration in response to injury. Cold plasma-mediated directional single cell migration, as observed in fibroblasts, could therefore be credited to CAP mediated induction of NF2 and CD44.

For GM Fbs in monoculture, we observed a decrease in cell migration with 30s treatment but an increase with 10s CAP treatment. This could be due to the differential sensitivity of keratinocytes and fibroblasts towards H_2O_2 [185]. However, we observed that keratinocytes cocultured with fibroblasts showed an improved cell migration (figure 4.8). Therefore, each cell type might display a specific treatment window for CAP treatment, where under optimal conditions, a stimulation of cell activities is possible.

Coculture mimics real skin more closely due to the inclusion of both keratinocytes and fibroblasts. As CAP treatment showed a better stimulation effect on keratinocyte migration in coculture, the cross talk between these two different cell types and the influence of CAP on these cells come into focus. Many growth factors and cytokines are released from fibroblasts after injury, and this could provide an explanation for the acceleration of coculture in wound closure [186, 187]. In a previous study by Seo et al. [188], HaCaT cell motility increased when HaCaT cells and fibroblasts were cultured together. This was mainly attributed to a synergistic effect where HaCaT cells showed an increased expression of TGF- β and fibroblasts showed an increased expression of Cyr61 [189]. Keratinocytes in direct contact with fibroblasts also showed enhanced migratory rate due to HB-EGF produced by IL-1 and TGF β stimulated fibroblasts [187]. Therefore, these and numerous other recent studies, have emphasized the importance of synergistic interaction between keratinocytes and fibroblasts. Hence, a better stimulation effect on cell migration upon CAP treatment is justified compared to monocultures.

Dynamic interactions between the secreted factor and extracellular matrix components are essential for wound healing. Fibroblasts, as one of the key players in wound healing, remodel ECM molecules, and support re-epithelialization via cell migration and motility [176]. In GM Fbs, we observed an increase in collagen molecules (specifically COL4, COL5, COL6, COL7, COL 15 and COL12) after CAP treatment (table 4.2). COL7 is secreted by dermal fibroblasts and is crucial for wound re-epithelialization. COL7A1 has been found to directly regulate keratinocyte cell migration [190]. Therefore, the increase in COL7A1 in dermal fibroblasts may also attribute to the increased migration in co culture. Cold plasma also significantly upregulated MMP 13, MMP 14, TIMP-2, MMP 3 molecules in dermal fibroblasts (table 4.2), which are known for their impact on remodeling of dermal tissue. However, metalloproteinase like MMP 8, MMP 9 were downregulated indicating a possible reduction of elevated level of these proteins, as often observed in chronic wounds. MMP 13 are expressed in leading edges of migratory epithelial cells in a cutaneous wound healing mice model and plays an important role in keratinocyte migration, angiogenesis and contraction in wound healing [191]. MMP 13 is activated by MMP 3, MMP 14 and MMP 2 molecules [192, 193]. Upregulation and activation of MMPs in GM Fbs could therefore have a synergistic effect on keratinocyte migration in coculture. Tight junctional proteins are also important for directional migration of epithelial cells, endothelial chemotaxis and barrier integrity [194]. TJP 1 was shown to regulate the cell migration, barrier formation and angiogenesis in human dermal microvascular endothelial cells (HDMEC) [194]. TJP-1 is also present at the leading edge of migrating fibroblasts in the corneal fibroblast scrape wound model. An upregulation of TJP-1 and TJP-2 expression in GM Fbs observed after 60s CAP treatment (table 4.1), hence supports the accelerated healing in coculture. In line with our observation, Schmidt et al. also showed that periodic exposure of CAP on keratinocytes could significantly upregulate TJP-1 up to 6 weeks [195]. CAP exerts its effect separately on dermal fibroblasts and keratinocytes and also influences their synergistic interaction and crosstalk in coculture by differentially regulating these matrix molecules.

Integrins are cell adhesion molecules and are responsible for proliferation, migration, differentiation and gene expression [196]. In our real time PCR experiments (table 4.2), we observed an upregulation of integrins namely ITGA3, ITGB2 and ITGB4. The adhesive nature of integrin allows them to bind with extracellular matrix proteins like laminin, collagen, vitronectin, fibronectin etc. [196] which were also differentially expressed upon cold plasma treatment in fibroblasts. Most of the laminin chains (LAMA3, LAMC1 etc.) remained unaltered (supplementary data, table 4), however, several collagen moieties (COL4, COL7 etc.) and vitronectin were significantly upregulated upon plasma treatment, which in patients would be a good indicator for a wound healing supported by the formation of new connective tissue. Several other adhesion molecules like Cadherin 1, catenin, PECAM1, VCAM1 were also differentially regulated upon 60s CAP treatment in GM Fbs. Together, these results suggest that, CAP could influence genes coding for proteins related to transmembrane molecules, cell-cell adhesion, cell-matrix adhesion, and a number of other ECM molecules which ultimately contribute to accelerated healing in coculture.

We also compared the effect of direct and indirect CAP treatment on cell migration in HaCaT alone and cocultured with fibroblasts (figure 4.13). We could observe that, compared to direct treatment, both 10s and 30s indirect CAP treatment accelerated cell migration in HaCaT mono and coculture. This can be attributed to the composition of direct and indirect CAP treatment. Direct CAP treatment exerts the effect of UV rays, electrical field, several other short and long lived reactive species such as $\bullet\text{NO}$, $\bullet\text{OH}$, $\text{O}_2\bullet\text{-}/\bullet\text{OOH}$, as well as non-radical chemical compounds, such as singlet oxygen $^1\text{O}_2$ [197] which could impose a direct oxidative stress on HaCaT cells and in coculture. Whereas indirect plasma treatment would primarily exert the effect of stable long-lived reactive species such as H_2O_2 , NO_2^- , and NO_3^- , produced upon interaction of CAP with the medium.

In HaCaT cells, as observed in figure 4.12, both 10 and 30s direct CAP treatment exposed a negative effect on cell migration. Cell migration was stunted when co culture was treated with 30s direct CAP treatment, however 10s direct CAP treatment induced cell migration, though the differences were not statistically significant. With increase in plasma treatment time the intracellular ROS generation also increases in HaCaT cells [198]. We also observed a treatment time-dependent increase of intracellular ROS production both in HaCaT and fibroblasts (figure 4.2), even though compared to positive control, 100 μM H_2O_2 , the fold change was insignificant. So, essentially it is a balance between the cumulative redox species posed to cells which determines CAP mediated effect on cell migration. Persistent short- and long-lived reactive species, as found in longer direct treatments generate an imbalance where the free reactive species are higher than the body's antioxidant system and therefore delays cell migration. Thus, 30s direct CAP treatment probably imparts an oxidative stress which is not evident upon 10s plasma treatment. Hence, we observe a delayed cell migration rate with longer plasma treatment time.

5.2 NAC abrogates CAP mediated cell migration

NAC is a thiol, mucolytic agent and a precursor of L- cysteine and reduced glutathione (GSH) and acts as a free radical scavenger of OH , H_2O_2 and O_2^- . NAC directly reacts with the radical species and scavenges them. However, NAC is a poor scavenger and the antioxidant and cytoprotective effect of NAC has been investigated by Ezerina et al [199]. In their study they showed that cysteine is desulfurated to generate hydrogen sulfide, which in turn is oxidized to sulfane sulfur species, predominantly within mitochondria. These sulfane sulfur species are the actual mediators of the immediate antioxidative and cytoprotective effects provided by NAC [199]. The in vivo antioxidant activity of NAC is attributed to its ability to replenish depleted GSH pools [200]. Recently, another mechanism of NAC antioxidant activity has been considered. NAC has the ability to disrupt thiolated proteins, the free thiol groups have better antioxidant effect than NAC and boosts GSH synthesis thus exerting the indirect antioxidant effect of NAC [200].

After making scratches, HaCaT cells in monoculture and cocultured with GM Fbs were incubated with untreated and CAP treated medium in combination with NAC. NAC could abrogate CAP stimulated cell migration in all three settings. We observed that NAC significantly reduced the cell migration rate in both monoculture and coculture of keratinocytes (figure 4.10, 4.11). NAC can exclusively disrupt cell migration in keratinocytes [201], fibroblast [202] as well as in coculture. Similar to our results, Loo et al. found that in a coculture model, where H₂O₂ could improve re-epithelialization of keratinocytes, 5 mM NAC could prevent it [185]. The delay in the cell migration rate that we observed upon NAC treatment could be partially accredited to its effect on signaling molecules. NAC could significantly reduce H₂O₂ induced collagen production in oral mucosal cells [203]. In a model of tissue fibrosis, it was observed that NAC abrogated TGF- β signaling in fibroblasts [204]. NAC treatment suppressed p38 phosphorylation and IL-6 production in HaCaT cells [205]. NAC could also significantly downregulate the production of VEGF in basal human keratinocytes [206]. Therefore, the exact mechanism on how and why NAC suppresses cell migration in HaCaT cells and in coculture is not self-explanatory. But, NAC probably suppresses growth factors, extracellular matrix molecules, interleukins and MAP kinases which can abrogate CAP-mediated cell migration in HaCaT cells and in coculture.

In summary, it could be shown that short-term CAP treatment could accelerate cell migration in coculture and has an impact on the synergistic interactions between keratinocytes and fibroblasts. It effects on extracellular matrix molecules, cell adhesion molecules which possibly show a cumulative positive effect on keratinocyte cell migration. NAC could disrupt this CAP mediated cell migration, indicating that CAP-generated reactive species trigger stimulation of cellular motility.

5.3 Effect of CAP on metabolic activity

In this work, cellular viability/metabolic activity of monocultures HaCaT, GM Fbs and coculture was investigated after 10, 30 and 60s CAP treatment. Cell viability was determined by the Alamar Blue assay, and as shown in figure 4.3, we observed a significant decrease in cell viability in all three different cell set ups 3 hours after a 60s CAP treatment. In fact, 24 hours after treatment, GM Fbs showed a further significant drop in metabolic activity after both 30 and 60s treatment. Previous studies have already pointed out that high amounts of ROS/RNS species can affect human cells and lead to cell death and reduction in cell viability and proliferation [207]. This results are in accord with the previous observations where Schmidt et al. have shown that 24 hours after 180s long-term CAP treatment in HaCaT cells, dead cells percentage increased to almost 1.5-fold [208]. Longer than 25s CAP treatment could also significantly decrease cell viability in L929 murine fibroblasts. However, a treatment time of 5-15 s could improve cell viability in L929 cells [209]. Consequently, the difference in cell viability in different cell types could be attributed

5. Discussion

to the difference in plasma source, scarcity of standardized conditions, plasma treatment time, plasma treatment distance and type of the cell. It was quite apparent from our data and previous literature that, short term CAP treatment (like 10s) was not harmful for the cells and there was no significant reduction in metabolic activity in all the three cell types even after 24 hours. However, a longer treatment time like 60s could immediately decrease the metabolic activity within 3 hours. Even though HaCaT cells could restore the metabolic activity 24 hour after treatment, GM Fbs could not restore the metabolic activity when cultured as monocultured cells. In fact, it resulted in a drop of approximately 50% in metabolic activity after long term CAP treatment. Coculture of keratinocytes and fibroblasts was comparatively resistant towards the plasma treatment, and like HaCaT cells, these cells could restore the cell viability 24 hours after all the treatment types.

NAC, the well-known scavenger of redox species was tested for its capability to restore the metabolic activity in all the cell types. In LPS induced RAW 264.7 macrophages, NAC significantly reduced cell death and counteracted the effect of oxidative stress inducing agent and improved cell viability [210]. Even in human primary gingival fibroblasts, high NAC concentration (5-10 mM) could significantly reduce cell death[211]. In accordance with the previous literature, NAC significantly restored the metabolic activity in both monocultures of fibroblasts and keratinocytes and in their coculture. In our studies, NAC alone did not significantly increase metabolic activity in HaCaT and coculture, but in GM Fbs, NAC alone could significantly improve metabolic activity 3 hours after treatment. As a positive control 60 μM H_2O_2 was used in this metabolic activity experiment (figure 4.4). 60 μM H_2O_2 decreased cell viability in both the monoculture and coculture 3 hours after treatment. But, when the cells were treated with H_2O_2 in combination with NAC, metabolic activity was restored. 24 hours after plasma treatment, metabolic activity was reduced in all the three cell set ups, but NAC significantly counteracted the effects of CAP treatment and restored the metabolic activity in all the three experimental set ups. This protective effect of NAC could be attributed to its direct scavenging properties or de novo synthesis of intracellular GSH pool with NAC as a precursor. Apart from 2.5 mM NAC, metabolic activity was also tested with 5mM NAC, and the results were identical to 2.5 mM NAC treatment (data not shown).

In summary, it could be shown that shorter CAP treatment did not have a significant effect on the metabolic activity. However, longer CAP treatment (60s) could significantly reduce the metabolic activity, which could be restored when cells were treated in combination with 2.5mM NAC.

5.4 Effect of CAP on HIPPO signaling pathway and paracrine signaling

CAP showed a better stimulation effect on cell migration in coculture compared to HaCaT monoculture. This indicates a signaling cross talk between keratinocytes and fibroblasts in coculture which is under CAP influence. To more thoroughly assess the signaling axis, we investigated signaling pathways involved in tissue homeostasis and regeneration. In this context, we investigated HIPPO signaling pathway in both the cell types which play a pivotal role in tissue homeostasis and regeneration.

5.4.1 CAP modulated activation of YAP-CTGF-Cyr61

YAP is a multifunctional adapter protein that possesses one coactivator domain. It is the major nuclear executor of the HIPPO signaling pathway [212]. While the upstream signaling kinases of HIPPO pathway are inactivated, YAP moves to nucleus, binds to gene enhancer elements in complex with a TEAD TF, interacting with chromatin remodeling factors and modulating RNA polymerase II to drive or repress the expression of target genes, which prominently include cell migration regulators [213].

YAP is highly expressed and predominantly nuclear in the early embryonic epidermal progenitors, and is essential for the proliferative capacity of progenitors and the development of the epidermis [214]. Deletion of YAP leads to a reduction of cell growth, inhibition of keratinocyte differentiation, and delay in wound healing [88]. Therefore, the role of YAP in wound healing is of utmost importance. In our study, we found an upregulated mRNA expression of YAP in GM Fbs upon CAP treatment. From our gene expression data, we also observed an upregulation of WWC1 in GM Fbs (table 4.1), an upstream regulator of YAP. WWC1 stimulates the phosphorylation of LATS1/2 on their hydrophobic motif. Its overexpression stimulates the phosphorylation of YAP and deletion reduces the phosphorylation [215]. In GM Fbs, we could observe that both LATS1/2 were upregulated upon CAP treatment (table 4.1). LATS1/2 can phosphorylate YAP/TAZ leading to its inactivation and cytoplasmic sequestration. Upon phosphorylation by upstream LATS kinases, YAP is associated with 14-3-3 protein and sequestered in the cytoplasm. But recent studies show that LATS-dependent phosphorylated YAP can be retained in the nucleus and is not necessarily exported to the cytoplasm [216]. However, in our settings, we did not observe any significant change in YAP phosphorylation in fibroblasts upon plasma treatment. We also quantified the nuclear-cytoplasmic distribution of YAP with immunofluorescence, as this distribution is a key determinant of its activity and is a major target of their regulation. Both untreated and 30s plasma treatment showed comparable cellular distribution of YAP. A minimal significant decrease in nuclear distribution of YAP upon 10s plasma treatment in GM Fbs was observed further indicating that YAP molecules are dynamic. Several studies describe that YAP molecules are not static, rather they

dynamically shuttle between cytoplasm and nucleus [217-220]. This might explain why we observe the equivalent distribution of YAP in control and plasma treated cells.

Reactive species play an important role in YAP target gene CTGF and Cyr61 induction. H₂O₂ and hydroxyl radicals induced CTGF expression in human lens epithelial cells [221]. CTGF was also upregulated in retinal pigment epithelial cells upon redox stimulation [222]. As observed in these studies, incubation with CAP generated reactive species stimulated the mRNA expression of CTGF in GM Fbs compared to control (figure 4.14). Protein expression of CTGF was also upregulated in GM Fbs (figure 4.17). CTGF promotes cell migration and adhesion by binding to integrin receptors on cell surface. Upregulation of integrin like ITGB4, ITGB2 and ITGA3 upon plasma treatment (table 4.2) could possibly link towards the CTGF- integrin signaling. Integrin activation leads to ERK and p38 phosphorylation, activation of F actin and Paxillin resulting in actin reorganization [223]. Integrin activation can also potentiate focal adhesion formation and cellular migration by stimulating FAK [99]. Even though we have not tested the expression of FAK, a possible crosstalk of CTGF-integrin FAK signaling could be ventured based on these results.

Cyr61 is also expressed in dermal fibroblasts during cutaneous wound healing. Upon CAP treatment, Cyr61 was induced at protein and gene level in GM Fbs. Similar to CTGF, Cyr61 also binds with the integrin receptors and mediates adhesion of dermal fibroblasts, VSMCs and platelets [97]. Cyr61 also binds to vitronectin with high affinity [224], which was also upregulated in our results (table 4.2). Several cell adhesion molecules like VCAM1, VTN, cadherins were differentially regulated (table 4.2). This indicate that Cyr61 might upregulate cell adhesion molecules. Cyr61 enhances endothelial cell adhesion, migration, proliferation and microtubule formation, by directly binding to $\alpha\beta3$ receptor [97]. Even though we observed an increased expression of Cyr61 in our data (figure 4.16, 4.17), gene expression of ITGB3 or ITGA5 remained unaltered in fibroblasts (supplementary data, table 4).

In HaCaT cells, we found an increase in YAP mRNA expression, though not significant. Interestingly, nuclear YAP is identified in basal cells throughout the wound healing zones of regenerative epidermis and is present is the leading edges of the wound where keratinocytes migrate as a sheet [213]. We further checked the phosphorylation status of YAP in HaCaT cells compared to total YAP. We found an increase in phosphorylated YAP compared to total YAP in HaCaT cells. In accordance with the canonical model, phosphorylated YAP is retained in the cytoplasm, probably which is why we observed that, YAP target genes, CTGF and Cyr61 are minimally transcribed in HaCaT cells. In HaCaT cells CTGF protein expression was slightly increased and Cyr61 was not detected. This is similar to previous study where Seo et al. showed that Cyr61 is not detected in keratinocytes, but was present in fibroblast and coculture [189]. Thus, our results clearly indicate a paracrine signaling based on the HIPPO mediated signaling molecules which is initiated from the fibroblasts upon CAP treatment, finally leading to an improvement in wound regeneration.

Previous studies have indicated the inhibitory effect of NAC on CTGF and Cyr61. Pre-incubation with 1 and 2 mM NAC significantly attenuated CTGF expression in GO orbital fibroblasts [225]. In human gingival fibroblasts and human dermal fibroblasts NAC could significantly impair the ability of TGF- β 1 to induce CTGF protein expression [226]. Upregulation of rapamycin induced CTGF was also completely blocked with 5mM NAC pretreatment in hepatic progenitor cells [227]. In good accordance with these findings, we detected a significant drop in CTGF mRNA expression in GM Fbs and HaCaT cells further pointing to a redox species mediated signaling triggered by CAP. NAC also reduced ROS mediated induction of Cyr61 and loss of intracellular type I collagen in human dermal fibroblasts [228]. In line with this study, we also detected a significant reduction of Cyr61 mRNA expression in both HaCaT and GM Fbs incubated with CAP treated medium in combination with NAC. This clearly shows the importance of a well-balanced ROS signaling in cells involved in wound healing – regulating the activity of the HIPPO pathway. Applying cold plasma at short-term treatment triggers keratinocytes slightly and a more pronounced activation could be found in fibroblasts. These CAP effects were even enhanced when cells were in coculture – implicating a paracrine effect between fibroblasts and keratinocytes triggered by a CAP activation of the HIPPO pathway.

5.4.2 Effect of CAP on paracrine signaling between keratinocytes and fibroblasts

As stated before, our coculture experiments clearly displayed the advantage of this 1:2 mixture of fibroblasts and keratinocytes in comparison to monocultures of those cells. This was reflected in higher survival rates, but also in an increased cell migration. An increasing number of studies are focusing on the paracrine signaling and interaction between keratinocytes and fibroblasts in the context of wound repair. To test our hypothesis that CAP-induced stimulatory effects in coculture are a result of paracrine crosstalk, we monitored the cell migration of HaCaT cells that were incubated with conditioned media harvested from CAP-treated GM Fbs (GM-Fb-CM) collected after 18 hours of CAP treatment.

Conditioned media acquired from GM Fbs stimulated cell migration to a greater extent compared to conditioned media from untreated fibroblasts or no conditioned media at all. This phenomenon supports our hypothesis that CAP induces paracrine signaling between these two cell types by releasing paracrine effectors and hence promoting keratinocyte migration. We hypothesized that both CTGF and Cyr61 are involved in paracrine signaling, as both of these molecules are secreted and are actively involved in wound healing cascade. Both CTGF and Cyr61 are transcriptionally activated by serum, platelet derived growth factor, TGF- β 1 and basic fibroblast growth factor [97]. CTGF is actually involved in early wound healing and repair. Topical application of CTGF also could accelerate diabetic wound closure rate compared to vehicle treated control wounds [95]. Loss of CTGF impairs efficient re-epithelialization. This is especially evident from the expression pattern of this

protein in acute and chronic wound. Significantly reduced levels of CTGF was found in chronic wounds compared to acute wounds, which further suggests the role of CTGF in therapeutic wound healing [229]. Like CTGF, Cyr61 is also strongly expressed in dermal fibroblasts of the granulation tissue during wound healing, coincident with wound contraction and ECM remodeling [97]. Both CTGF and Cyr61 can regulate the production of angiogenic molecules (VEGF, bFGF), MMPs and TIMPs which affect the integrity of ECM [91]. In accord with our hypothesis and existing literature, we demonstrated an increase in secreted CTGF and Cyr61 upon CAP treatment (figure 4.22). The increased secretion of CTGF and Cyr61 by CAP treated Fbs confirms that through their paracrine action they directly participate in wound healing of HaCaT cells.

We further tested our hypothesis by incubating HaCaT cells with recombinant human CTGF and Cyr61. Both recombinant CTGF and Cyr61 could significantly induce HaCaT cell migration (figure 4.23). The role of recombinant CTGF has been studied before by Seher et al [230]. They showed that human recombinant CTGF induces an inflammatory and wound healing response in primary tendon fibroblasts. Human recombinant CTGF could upregulate the transcription of several cytokines (IL-6, IL-8, CXCL1, and CXCL2) in human fibroblasts [231]. Exogenous addition of CTGF could also accelerate keratinocyte cell migration in a scratch wound model by phosphorylating ERK [232], which supports our cell migration studies (figure 4.23 a). In a coculture with both HaCaT cells and fibroblasts, secretion of Cyr61 from fibroblasts could significantly accelerate HaCaT cell migration, even when Cyr61 was not detected in HaCaT cells [233]. Combining these results, it is evident that, CTGF and Cyr61 secreted from CAP treated fibroblasts act as paracrine effectors in wound healing. These results confirm our hypothesis that CAP promotes a beneficial interaction between keratinocytes and fibroblasts that ultimately contributes to wound healing.

Here, for the first time, we demonstrated that CAP can stimulate a regenerative signaling pathway in dermal cells-namely the HIPPO pathway. We observed that the cold plasma-mediated effect on skin repair is mainly due to the activation of fibroblasts that when stimulated by CAP causes a paracrine stimulation of keratinocytes by releasing extracellular proteins as indicated by our coculture and migration experiments with conditioned media. Together, these results confirm the role of the HIPPO pathway in plasma-mediated wound healing that is dominantly triggered by long-living ROS that are generated by cold plasma. It also confirmed the negative effects of antioxidants on ROS mediated signaling in wound healing.

An overview of the impact of CAP treatment on the cellular redox signaling based on this data is provided in figure 5.1.

Figure 5.1 Schematic of keratinocyte activation by CAP modulated fibroblasts. The primary event in this scheme is the generation of reactive species in response to CAP treatment. These reactive species function as secondary messengers and stimulate the production of HIPPO signaling effectors such as CTGF in HaCaT and CTGF and Cyr61 by dermal fibroblasts in the vicinity. These extracellular matrix proteins and signaling molecules that are released from fibroblasts in turn activate keratinocytes, accelerate migration, and promote wound healing. This figure is adapted from [212].

In conclusion, this study provides the mechanistic insight on how CAP regulates a regenerative signaling pathway (HIPPO) and paracrine interactions between keratinocytes and fibroblasts. A detailed expression profile of extracellular matrix and adhesion molecules reveals that CAP regulates several ECM and adhesion molecules which promote re-epithelialization, immune cell infiltration, and granular tissue maturation ultimately leading to wound healing. Overall, this study contributes to a better understanding on the effect of CAP on re-epithelialization and regeneration which promote wound healing, based on the regenerative modulation of cells by HIPPO signaling.

6. Outlook

CAP treatment results into a complex cross talk between redox signaling pathways in mammalian cells via the impact of short- and long-lived reactive species. Here in this study, for the first time, we provided a mechanistic insight on how CAP activate HIPPO signaling in dermal fibroblasts. Although keratinocytes produced small amounts of CTGF, it is predominantly the secretion of CTGF and Cyr61 from dermal fibroblasts which influences the activation of keratinocytes through paracrine signaling and improves cell migration. During the course of this investigation, we could pinpoint to several molecules that are important in CAP-mediated wound healing.

Our RT-PCR data revealed an upregulation of HIF-1 α in GM Fbs and HaCaT cells. Previous studies have already demonstrated a functional link between YAP and HIF-1 α . [86]. Even though we observed an increase in HIF-1 α in both GM Fbs and HaCaT cells, we did not check the stability of this protein upon knockdown of YAP. CAP could also induce heme oxygenase-1 (HMOX-1), a downstream target of HIF-1 α , in both keratinocytes and fibroblasts [178, 234]. Thus, a possible signaling of YAP-HIF-1 α - HMOX-1 should be further explored.

Several metalloproteinase (ADAMTS, MMPs), cell adhesion molecules (integrin, cadherin), extracellular matrix molecules were differentially expressed upon cold plasma treatment (table 4.2). In order to validate these observations, the protein profiles should be examined and the role of these factors in immune cell infiltration, granular tissue maturation and re-epithelialization should be further explored. HIPPO signaling effectors were investigated by RT² PCR array and we observed differential regulation of 59 genes (FAT family, LATS family, TEAD family, Cyclins etc.) upon cold plasma treatment (table 4.1). Thus changes in the protein level of these genes should be investigated as HIPPO signaling seems to be the major CAP activated pathway, involved in re-epithelialization and wound healing. Initial results already point to several signaling pathway that can be explored in future. For example, FAT1 and FJX1 were upregulated in our RT-PCR data. FAT1 is an upstream regulator of HIF-1 α [235] and FJX1 is responsible for its stabilization [236]. These molecules might be involved in the signaling process. Overall, HIF-1 α seems to be another CAP-induced major regulator that needs to be studied in future in context of wound healing.

This study was performed in selected cell lines, however various other cell types are involved in wound healing. Thus an animal model mimicking either an acute or a chronic wound should be employed to study the complex interaction of various cell types in respect to their reaction to plasma treatment.

7. Summary

Reactive species play an essential role in orchestrating wound healing responses. They act as secondary messengers and drive redox-signaling pathways that are involved in the hemostatic, inflammatory, proliferative and remodeling phases of wound healing. Cold plasma produces a profusion of short- and long-lived redox species that promotes wound healing, however, until today, the knowledge of CAP mediated wound healing remained scarce. In this thesis, CAP mediated wound healing mechanism and their effect on extracellular matrix and adhesion molecules have been investigated. To this end, a keratinocyte cell line (HaCaT), skin fibroblast cell line (GM Fbs) and an *in vitro* coculture model including both HaCaT and GM Fbs at a 2:1 ratio, were employed to investigate the cross talk between these two skin cell types.

We examined the impact of CAP on extracellular matrix proteins and cell adhesion molecules in GM Fbs and observed a significant impact of cold plasma treatment on the expression level of collagen moieties, cell adhesion molecule like integrin, cadherin, versican, MMPs as well as extracellular matrix proteins.

Moreover, scratch assays with monocultures of HaCaT, GM Fbs and coculture of these two cell types were performed. We detected that, CAP accelerated the migratory capability of HaCaT cells cocultured with fibroblasts. In fact, compared to HaCaT monoculture, a significant acceleration on cell migration was observed in coculture upon CAP treatment. NAC, a potent antioxidant could abrogate this CAP-stimulated cell migration in coculture, further pointing towards the importance of well-orchestrated reactive species in wound healing. To better understand this CAP-mediated effect on cell migration, we examined the signaling pathways involved in tissue homeostasis and regeneration. We checked the HIPPO signaling pathway and observed an upregulation of several signaling molecules at transcriptional level in GM Fbs upon CAP treatment.

YAP is the central nuclear executor of HIPPO signaling pathway. YAP was upregulated in both HaCaT cells and GM Fbs. The major downstream effectors of the HIPPO signaling pathway (CTGF and Cyr61) were also upregulated in dermal fibroblasts at both transcriptional and protein level. However, administration of antioxidant NAC inhibited CAP-mediated wound healing and abrogated the gene expression of the HIPPO downstream effectors. These results confirm that the upregulation of YAP-CTGF-CYR61 axis is due to CAP-generated redox species. In HaCaT cells, both CTGF and Cyr61 was minimally transcribed. Even though CTGF was rarely detected in HaCaT cells on the protein level,

7. Summary

Cyr61 remained undetected. This again shows the importance of the cross talk between fibroblasts and keratinocytes.

The coculture with the inclusion of fibroblasts showed an accelerated migration rate, compared to HaCaT monoculture which specifies a cross talk between these two cell types. Thus, monoculture of HaCaT cells were incubated with CAP-treated and untreated fibroblast conditioned medium. Interestingly, we observed that HaCaT cells exhibited an improved cell migration rate when incubated with CAP-treated fibroblast-conditioned media compared to that observed after incubation with untreated media. Upon investigation, an induction of CTGF and Cyr61 secretion was observed upon CAP treatment in the fibroblast-conditioned media. Furthermore, exposure to recombinant CTGF and Cyr61 could also significantly improve HaCaT cell migration which confirms that CAP mediated accelerated cell migration is due to activation of YAP-CTGF-Cyr61 axis.

In conclusion, this study revealed a completely new mechanical insight of CAP mediated wound healing. Along with several other ECM molecules, CAP activates a regenerative signaling pathway i.e., HIPPO signaling pathway in dermal fibroblasts at the onset of wound healing. Dermal fibroblasts drive a paracrine interaction by secreting CTGF and Cyr61 in close vicinity of wound, resulting in accelerated keratinocyte migration and wound healing in coculture.

8. Zusammenfassung

Reaktive Spezies spielen eine wesentliche Rolle bei der Orchestrierung von Wundheilungsreaktionen. Sie wirken als sekundäre Botenstoffe und steuern Redox-Signalwege, die an den hämostatischen, entzündlichen, proliferativen und transformativen Phasen der Wundheilung beteiligt sind. Kaltes Plasma erzeugt eine Fülle von kurz- und langlebigen Redoxspezies, die die Wundheilung fördern. Das Wissen über die CAP-vermittelte Wundheilung ist jedoch noch rar. In dieser Arbeit untersuchten wir den CAP-vermittelten Wundheilungsmechanismus und seine Wirkung auf extrazelluläre Matrix- und Adhäsionsmoleküle. Zu diesem Zweck haben wir die Keratinozyten-Zelllinie (HaCaT), die Hautfibroblasten-Zelllinie (GM00637 Fbs) und ein In-vitro-Kokulturmodell ausgewählt, das sowohl HaCaT als auch GM Fbs im Verhältnis 2:1 um den cross-talk zwischen den beiden Zelltypen zu untersuchen.

Im Rahmen der vorliegenden Doktorarbeit wurde der Einfluss von CAP auf extrazelluläre Matrixproteine und Zelladhäsionsmoleküle in GM Fbs untersucht. Dabei konnten unterschiedliche Genexpressionsniveaus mehrerer Kollagene, Zelladhäsionsmoleküle wie Integrin, Cadherin, Versican, sowie MMPs und extrazelluläre Matrixproteine nach der Behandlung mit kaltem Plasma beobachtet werden.

Darüber hinaus wurden Scratch-Assays mit Monokulturen von HaCaT, GM Fbs und Kokultur dieser beiden Zelltypen durchgeführt. Dabei wurde festgestellt, dass CAP die Migrationsfähigkeit von mit Fibroblasten kokultivierten HaCaT-Zellen beschleunigt. Tatsächlich wurde im Vergleich zur HaCaT-Monokultur eine signifikante Beschleunigung der Zellmigration in der Kokultur nach CAP-Behandlung beobachtet. NAC, ein starkes Antioxidans, könnte diese CAP-stimulierte Zellmigration in der Kokultur aufheben, was die Bedeutung einer gut ausbalancierten Steuerung der reaktiven Spezies für die Wundheilung weiter unterstreicht. Um diesen CAP-vermittelten Effekt auf die Zellmigration zu verstehen, wurden die Signalwege, die an der Homöostase und Regeneration des Gewebes beteiligt sind, insbesondere der HIPPO-Signalweg, untersucht. Dabei wurde eine Hochregulation auf Transkriptionsebene von Signalmolekülen in GM Fbs nach CAP-Behandlung beobachtet.

YAP ist der zentrale nukleare Vermittler des HIPPO-Signalwegs. YAP wurde sowohl in HaCaT Zellen als auch in GM Fbs hochreguliert. Die wichtigsten nachgeschalteten Effektoren des HIPPO-Signalwegs (CTGF und Cyr61) waren in dermalen Fibroblasten sowohl auf Transkriptions- als auch auf Proteinebene hochreguliert. Die Verabreichung des Antioxidans NAC konnte jedoch die CAP-vermittelte Wundheilung hemmen und die

Genexpression der nachgeschalteten HIPPO-Effektoren aufheben. Diese Ergebnisse bestätigen, dass die Hochregulation der YAP-CTGF-CYR61-Achse auf CAP-erzeugte Redoxspezies zurückzuführen ist. In HaCaT-Zellen allein wurden sowohl CTGF als auch Cyr61 minimal transkribiert. Obwohl CTGF in HaCaT-Zellen (Proteinspiegel) nur minimal nachgewiesen wurde, blieb Cyr61 unentdeckt. Dies zeigt erneut die Bedeutung des parakrinen cross talks zwischen Fibroblasten und Keratinozyten.

Die Kokultur unter Einbeziehung von Fibroblasten zeigte eine beschleunigte Migrationsrate im Vergleich zur HaCaT-Monokultur, was einen *cross talk* zwischen diesen beiden Zelltypen nahelegt. Daher wurde die Monokultur von HaCaT Zellen mit CAP-behandeltem und unbehandeltem Fibroblasten-konditioniertem Medium inkubiert. Interessanterweise beobachteten wir eine im Vergleich mit der nach Inkubation mit unbehandelten Medien deutlich verbesserte Zellmigrationsrate der HaCaT-Zellen bei Inkubation mit CAP-behandelten Fibroblasten-konditionierten Medien. Bei der Untersuchung wurde bei CAP-Behandlung in den Fibroblasten-konditionierten Medien eine Induktion der CTGF- und Cyr61-Sekretion beobachtet. Darüber hinaus könnte die Exposition gegenüber rekombinantem CTGF und Cyr61 auch die HaCaT-Zellmigration signifikant verbessern, was bestätigt, dass die CAP-vermittelte beschleunigte Zellmigration auf die Aktivierung der YAP-CTGF-Cyr61-Achse zurückzuführen ist.

Zusammenfassend ergab diese Studie einen völlig neuen mechanistischen Einblick in die CAP-vermittelte Wundheilung. Zusammen mit der Regulation mehrerer ECM-Moleküle, aktiviert CAP einen regenerativen Signalweg, nämlich den HIPPO-Signalweg in dermalen Fibroblasten zu Beginn der Wundheilung. Dermale Fibroblasten steuern eine parakrine Wechselwirkung, indem sie CTGF und Cyr61 in unmittelbarer Nähe der Wunde sekretieren, was zu einer beschleunigten Keratinozytenmigration und Wundheilung in der Kokultur führt.

- Figure 4.1** CAP generated hydrogen peroxide production in RPMI medium. Concentration of H₂O₂ after 10, 30 and 60s of plasma treatment with kINPen MED operated at 5 SLM with argon flux. No plasma treatment served as the negative control. Data are presented as mean ± S.D. from two independent experiments. Statistical comparisons are performed using one-way ANOVA. 39
- Figure 4.2** Effect of CAP on intracellular ROS levels. Intracellular ROS production was measured by 2, 7'-diclorofluorescein (DCF) fluorescence in (A) HaCaT cells and (B) GM Fbs. Data are presented as mean ± S.D. from two independent experiments, each performed in technical quadruplets. Statistical comparisons were performed using one-way ANOVA. 40
- Figure 4.3** Influence of CAP on metabolic activity of mono and coculture. The metabolic activity of HaCaT cells, GM Fbs, and coculture after 3 h in response to 10, 30, and 60s of CAP treatments. Untreated RPMI served as control (A). Metabolic activity of the same cell types after 24 h of CAP treatment (B). Data are presented as mean ± SD of three independent experiments performed in triplicate. Statistical comparisons were performed using one-way ANOVA. 41
- Figure 4.4** Effect of NAC on metabolic activity after 3 h of CAP treatment. Metabolic activity of HaCaT cells, GM Fbs, and coculture after 3 h incubation with 2.5mM NAC alone or in combination with CAP-treated media. Data are presented as mean ± SD from at least three independent experiments performed in triplicate. Statistical analysis was performed using one-way ANOVA. 42
- Figure 4.5** Effect of NAC on metabolic activity of CAP treated cells after 24 h. Metabolic activity of HaCaT cells, GM Fbs, and coculture after 24 h incubation with 2.5mM NAC alone or in combination with CAP-treated media. Data are presented as mean ± SD from at least three independent experiments performed in triplicate. Statistical analysis was performed using one-way ANOVA. 43
- Figure 4.6** Influence of CAP on HaCaT cell migration. The representative time course of wound closure in untreated and indirect CAP treated HaCaT cells is shown in (A). The summation of relative wound density of untreated and CAP treated HaCaT cells are shown at specific time points 6, 12, 18 and 24 h (B). Wound closure images at time 0,

12 and 24 h in untreated and CAP treated HaCaT cells (C). Data are presented as mean± SD from three independent experiments. Statistical comparisons were performed using two-way ANOVA. 45

Figure 4.7 Influence of CAP on cell migration of GM Fbs. The representative time course of wound closure in untreated and indirect CAP treated GM Fbs is shown in (A). The summation of relative wound density of untreated and CAP treated fibroblasts are shown at specific time points 6, 12, 18 and 24 h (B). Wound closure images at time 0, 12 and 24 h in untreated and CAP treated GM Fbs (C). Data are presented as mean ±SD from three independent experiments. Statistical comparisons were performed using two-way ANOVA. 47

Figure 4.8 Influence of CAP on cell migration in coculture. The representative time course of wound closure in untreated and indirect CAP treated coculture is shown in (A). The summation of relative wound density of untreated and CAP treated coculture are shown at specific time points 6, 12, 18 and 24 h (B). Wound closure images at time 0, 12 and 24 h in untreated and CAP treated coculture (C). Data are presented as mean ±SD from three independent experiments. Statistical comparisons were performed using two-way ANOVA. 49

Figure 4.9 Comparison of relative wound density between untreated and CAP-treated HaCaT cells and coculture. (A), (B) and (C) details the comparative analysis of cell migration between HaCaT mono culture and co culture after incubation with untreated, 10s and 30s CAP treated medium at 6, 12, 18 and 24 h. Data are presented as mean ± SD from three independent experiments. Statistical comparisons are performed with two-way ANOVA. 50

Figure 4.10 Effect of NAC on HaCaT cell migration. (A) details the relative wound density of HaCaT cells after treatment with NAC alone or in combination with CAP-treated media at 6, 12, 18, and 24 h. (B) depicts the representative time course of wound closure in HaCaT cells treated with CAP alone or in combination with 2.5mM NAC. Data are presented as mean ± SD of three independent experiments performed in triplicate. Statistical comparisons were performed using two-way ANOVA. 51

Figure 4.11 Effect of NAC on coculture cell migration. (A) details the relative wound density of coculture after treatment with NAC alone or in combination with CAP-treated media

at 6, 12, 18, and 24 h. (B) depicts the representative time course of wound closure in coculture treated with CAP alone or in combination with 2.5mM NAC. Data are presented as mean \pm SD of three independent experiments performed in triplicate. Statistical comparisons were performed using two-way ANOVA. 52

Figure 4.12 Influence of direct CAP treatment on cell migration in HaCaT and coculture. (A) and (B) depicts the summation of relative wound density in HaCaT monoculture and coculture upon untreated, 10 and 30s direct CAP treatment at specific time points 6, 12, 18 and 24 h. EGF (10ng/ml) served as the positive control. Data is presented as mean \pm SD from two independent experiments, each with triplicates. Statistical comparisons were performed with two-way ANOVA. 53

Figure 4.13 Comparison of direct and indirect CAP treatment in HaCaT cells and coculture. (A) and (B) depicts the comparison of relative wound density between direct and indirect CAP treatment in coculture at 6, 12, 18 and 24 h. (C) and (D) details the comparison of relative wound density between direct and indirect CAP treatment in HaCaT cells at 6, 12, 18 and 24 h. Dara are presented as mean \pm SD from two independent experiments, each in triplicates. Statistical comparison is performed with two-way ANOVA. 54

Figure 4.14 mRNA expression of HIPPO signaling effectors in GM Fbs after CAP treatment. Gene expression of YAP (A), CTGF (B) and Cyr61 (C) in GM Fbs measured 3, 6, 18, and 24 h after CAP treatment by qPCR and normalized to relative gene expression ($\Delta\Delta C_t$ values on a log 2 scale). The x-axis represents CAP treatment time and incubation time after plasma treatment. Data are represented as mean \pm SD of four independent experiments. Statistical analysis was performed using unpaired *t*-test with Welch's correction for multiple comparisons, along with normalization to the untreated control. 55

Figure 4.15 mRNA expression of HIPPO signaling effectors in HaCaT cells. Gene expression of YAP (A), CTGF (B) and Cyr61 (C) in HaCaT cells measured 3, 6, 18, and 24 h after CAP treatment by qPCR and normalized to relative gene expression ($\Delta\Delta C_t$ values on a log 2 scale). The x-axis represents CAP treatment time and incubation time after plasma treatment. Data are represented as mean \pm SD of three independent experiments. Statistical analysis was performed using unpaired *t*-test with Welch's correction for multiple comparisons, along with normalization to the untreated control. 56

- Figure 4.16** Effect of CAP on YAP protein expression. The relative phosphorylation level of YAP is shown in GM Fbs (A) and HaCaT cells (B). Quantification is performed from three independent blots. Representative blots are shown. The x-axis represents CAP treatment time and incubation time after plasma treatment. Data are represented as mean \pm SD of at least three independent experiments. Statistical analysis was performed using unpaired t-test with Welch’s correction for multiple comparisons, along with normalization to the untreated control. 57
- Figure 4.17** Effect of CAP on CTGF and Cyr61. CTGF and Cyr61 protein expression was enhanced after 10 and 30 s of CAP treatment in GM Fbs (A, B). CTGF expression slightly increased after 10 and 30 s of CAP treatments in HaCaT cells after approximately 3 h (C). Representative blots are shown. The x-axis represents CAP treatment time and incubation time after plasma treatment. Data are represented as mean \pm SD of at least three independent experiments. Statistical analysis was performed using unpaired *t*-test with Welch’s correction for multiple comparisons, along with normalization to the untreated control..... 58
- Figure 4.18** Gene expression of signaling molecules in crosstalk with YAP. Gene expression of signaling molecules in GM Fbs (A,C) and HaCaT cells (B,D) measured 3, 6, 12, 18, and 24 h after CAP treatment by qPCR and normalized to relative gene expression ($\Delta\Delta\text{Ct}$ values on a log 2 scale). The x-axis represents CAP treatment time and incubation time after plasma treatment. Data are represented as mean \pm SD of two independent experiments. Statistical analysis was performed using one-way ANOVA, along with normalization to the untreated control. 60
- Figure 4.19** Cellular distribution of YAP in HaCaT cells. HaCaT cells were incubated with untreated and CAP treated RPMI for 3 h. (A) Details the quantification of Nuclear YAP: Cytoplasmic YAP in HaCaT cells. Representative images of untreated and CAP treated HaCaT cells are showed in (B). Immunofluorescence detection was performed with the primary anti total YAP (mouse mAB, 1:500). Nucleus was stained with DAPI. Data are presented as mean \pm SD from two independent experiments, each in duplicates. At least 4 images were taken from each of the duplicates. Statistical analysis was performed with one-way ANOVA..... 62

- Figure 4.20** Cellular distribution of YAP in GM Fbs. GM Fbs were incubated with untreated and CAP treated RPMI for 3 h. (A) Details the quantification of Nuclear YAP: Cytoplasmic YAP in GM Fbs. Representative Images of untreated and CAP treated fibroblasts are showed in (B). Immunofluorescence detection was performed with the primary anti total YAP (mouse mAB, 1:500). Nucleus was stained with DAPI. Data are presented as mean \pm SD from two independent experiments, each in duplicates. At least 4 images were taken from each of the duplicates. Statistical analysis was performed with one-way ANOVA..... 63
- Figure 4.21** Effect of NAC on the YAP-CTGF-Cyr61 signaling cascade. Gene expression of YAP, CTGF, and Cyr61 in GM Fbs (A) and HaCaT cells (B) measured 18 h after CAP treatment by qPCR and normalized to relative gene expression ($\Delta\Delta$ Ct values on a log 2 scale). Data are presented as mean \pm SD from at least three independent experiments, and statistical analysis was performed using unpaired t-test with Welch’s correction. 65
- Figure 4.22** CAP enhances secreted CTGF and Cyr61 expression from GM Fbs. Secreted CTGF (A) and Cyr61 (B) (pg/ml) was analyzed by ELISA. Data are presented as mean \pm SD from two independent experiments, and statistical analysis was performed using one-way ANOVA..... 66
- Figure 4.23** Cell migration of HaCaT monoculture in presence of recombinant CTGF and Cyr61. Relative wound density in HaCaT cells was monitored after treatment with 10 and 50 ng/ml CTGF and 100 ng/ml and 1 μ g/ml Cyr61. (A) Details the summation of relative wound density upon treatment with recombinant 10 and 50 ng/ml CTGF. (B) Details of a representative time course analysis of CTGF mediated wound healing in HaCaT cells. (C) Depicts the summation of relative wound density upon treatment with recombinant 100 ng/ml and 1 μ g/ml Cyr61. (B) Details a representative time course analysis of Cyr61 mediated wound healing in HaCaT cells. Data are presented as mean \pm SD from three independent experiments, and statistical analysis was performed using two-way ANOVA. 67
- Figure 4.24** Effect of CAP on paracrine signaling between keratinocytes and fibroblasts. HaCaT cells were incubated with conditioned media harvested from untreated or 10 and 30 s CAP-treated GM Fbs. (A) Details the summation of relative wound density of HaCaT

cells upon treatment with untreated and CAP treated GM Fb CM. (B) Details a representative time course analysis of the same. Data are presented as mean \pm SD from three independent experiments, and statistical analysis was performed using two-way ANOVA. 68

Figure 4.25 PANTHER biological process classification of HIPPO genes analyzed by RT² PCR array..... 69

Figure 4.26 Gene ontology analysis of significantly upregulated genes of HIPPO signaling pathway. (A) Defines the MF classification, (B) defines the CC classification and (C) defines the BP classification. Top 5 terms of all the category have been provided here. 74

Figure 4.27 PANTHER Biological process classification of ECM and adhesion molecules, analyzed by RT² PCR array 75

Figure 4.28 Gene ontology analysis of significantly upregulated genes of ECM and adhesion array. (A) Defines the MF classification, (B) defines the CC classification and (C) defines the BP classification. Top 5 terms of all the category have been provided here. 79

Figure 4.29 Gene ontology analysis of significantly downregulated genes of ECM and adhesion array. (A) Defines the MF classification, (B) defines the CC classification and (C) defines the BP classification. Top 5 terms of all the category have been provided here. 80

Figure 5.1 Schematic of keratinocyte activation by CAP modulated fibroblasts. The primary event in this scheme is the generation of reactive species in response to CAP treatment. These reactive species function as secondary messengers and stimulate the production of HIPPO signaling effectors such as CTGF in HaCaT and CTGF and Cyr61 by dermal fibroblasts in the vicinity. These extracellular matrix proteins and signaling molecules that are released from fibroblasts in turn activate keratinocytes, accelerate migration, and promote wound healing. This figure is adapted from [212]...... 91

Supplementary Data

Figure i. Representative figure of cell migration assay of coculture with the ratio of 1:5 for GM Fbs: HaCaT cells. 10,000 GM Fbs and 50,000 HaCaT cells were seeded in the image lock plate 24 hours prior to the experiment. Cells were starved for about 18-20 hours and treated with 10s or 30s direct CAP treatment or incubated with untreated, 10s, 30s and 60s of CAP treated medium (indirect treatment). Compared to untreated control, indirect treatment (all 10, 30 and 60s) improved cell migration of the coculture. But direct treatment could not improve the cell migration compared to untreated control.

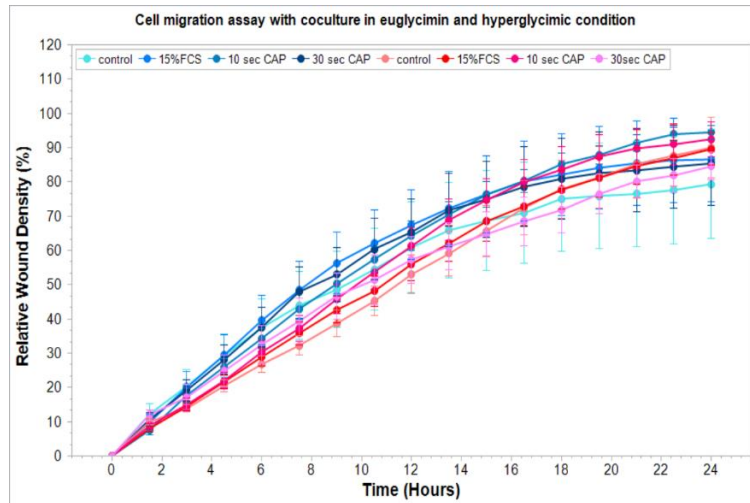

Figure ii. Representative figure of cell migration assay of coculture in euglycemic and hyperglycemic condition. The blue lines correspond to euglycemic condition and the pink lines to hyperglycemic condition. For euglycemic condition, normal RPMI containing 2gm/1000ml of D glucose was used. For hyperglycemia, additional 2.5gm glucose was added in the medium. Cell migration assay was performed with untreated, 15% FCS medium, 10s and 30s CAP treated medium. No significant difference in cell migration was observed between euglycemic and hyperglycemic condition.

Figure iii. Representative figure of cell migration assay of HaCaT cells in euglycemic and hyperglycemic condition. The blue lines correspond to euglycemic condition and the pink lines to hyperglycemic condition. Cell migration assay was performed with untreated, 15% FCS medium, 10s and 30s CAP treated medium. Cell migration tends to be faster in hyperglycemic condition compared to euglycemic condition.

Figure iv. Representative figure of cell migration assay of GM Fbs in euglycemic and hyperglycemic condition. The blue lines correspond to euglycemic condition and the pink lines to hyperglycemic condition. Cell migration assay was performed with untreated, 15% FCS medium, 10s and 30s CAP treated medium. No significant difference in cell migration was observed between euglycemic and hyperglycemic condition.

Figure v. Summation of relative wound density of HaCaT monoculture with untreated, 10ng/ml EGF and 15% FCS stimulation. Migration assay was monitored at 6, 12, 18 and 24 hours. Compared to control, EGF and 15% FCS accelerates cell migration, though not significant. Data is presented as mean \pm SD from three independent experiments, each in triplicate. Statistical analysis was carried out with two-way ANOVA.

Figure vi. Summation of relative wound density of GM Fbs with untreated (control), 10ng/ml EGF, 15% FCS and 10µg/ml Mitomycin C stimulation. Migration assay was monitored at 6, 12, 18 and 24 hours. Compared to control, EGF significantly accelerates cell migration. Mitomycin C also significantly decelerates the cell migration. Data is presented as mean ± SD from three independent experiments, each in triplicate. Statistical analysis was carried out with two-way ANOVA.

Figure vii. Summation of relative wound density of coculture with untreated (control), 10ng/ml EGF, 15% FCS and 10µg/ml Mitomycin C stimulation. Migration assay was monitored at 6, 12, 18 and 24 hours. Compared to control, EGF accelerates cell migration, though not significant. Mitomycin C significantly decelerates the cell migration. Data is presented as mean ± SD from three independent experiments, each in triplicate. Statistical analysis was carried out with two-way ANOVA.

(A)

(B)

Figure viii. Relative fold change of mRNA expression upon CAP treatment in GM Fbs (A) and HaCaT cells (B). Cells were treated for 10s, 30s and 60s. 3, 6, 12, 18 and 24 hours after the treatment RNA was isolated, cDNA was prepared and gene expression analysis for Stat3, TGF beta and MAPK 9 was carried out. Data is presented as mean \pm SD from two independent experiments. Statistical analysis was performed using one-way ANOVA, along with normalization to the untreated control.

Figure ix. Relative mRNA expression of Keratin-1 (KRT-1) 3, 6, 18 and 24 hours after indirect CAP treatment. HaCaT cells were treated for 10s, 30s and 60s. Compared to control, both 10s and 30s could significantly increase the KRT-1 mRNA expression at 3 hours. Data is presented as mean \pm SD from three independent experiments. Statistical analysis was carried out with one-way ANOVA.

Figure x. Relative mRNA expression of Transglutaminase 1 (TGM-1) 6 and 24 hours after direct CAP treatment. HaCaT cells were directly treated for 45s, 60s and 180s. Compared to control, both 45s and 90s could increase the TGM-1 mRNA expression at 6 hours. Data is presented as mean \pm SD from three independent experiments. Statistical analysis was carried out with one-way ANOVA.

Acknowledgements

First, I am grateful to Prf. Katharina Riedel and Prf. Michael Lalk for their guidance, trust and support of my PhD project. The fruitful discussions on the scientific results, their encouragement and advice motivated me in my PhD. Next, I would like to express my deepest gratitude to Dr. Kai Masur for giving me the opportunity to work in his group and supervising me in this interesting new topic 'Plasma Medicine'. He supported me throughout my work and gave me the scientific freedom to self-manage my work whenever required. Thank you for trusting on my ability and being positive on 'trying out experiments'. Next, I would like to thank Prf. Thomas von Woedtke for his constant encouragement on my project and his advice and thorough comments on the manuscript. It was quite reassuring to know that he is always up for discussions.

I further would like to thank my colleagues Liane Kantz and Felix Nießner for solving my experimental glitches. In addition, cheers to Anke Schmidt for giving directions on all real time related queries, Jan Wilm Lackmann for helpful discussions. I am thankful to my present and former group members Maria, Marieke, Vladimir for always putting up a positive atmosphere in the office. I would also like to appreciate all other researchers and colleagues at INP for their help and support.

Further, I am thankful to all my fellow PhDs in ZIK (Giuliana, Gabri, Marie, Basti, Johanna, Christina, Ramona, Juliana) for making my life a bit more colorful and enjoyable in Greifswald. Especially Giuliana, for being my go to person in Greifswald! My friends from Berlin, who always made me feel at home. The weekend trips to Berlin have given me a constant moral boost to continue my PhD here.

A big shout out to my whole family and friends from all over the world for being a part of my life and making it so much better!

Last but not the least, I am forever indebted to my parents for supporting me and believing me in all the decisions that I have taken in my life. The constant encouragement that I received from them have driven me to continue my studies abroad. Even though they are far way, I can always feel their love and support.

Finally, words will fall short to say thanks to my husband Wrijupan, who have stood like a pillar beside me for this last decade. Thank you for cheering me when it is needed, supporting me in difficult decisions, for believing me and most importantly for bearing with me through all the ups and downs in life. Thank you for being there!
