

SUPPLEMENTARY INFORMATION

Discovery of novel eGFR-associated multiple independent signals using a quasi-adaptive method

Sahar Ghasemi *et al.*

Content description:

Figures 1-57: Represent regional association plots for loci with replicated novel independent signals identified by the quasi-adaptive method. Three plots were shown for each locus. The **first plot** shows a regional association plot based on eGFR association analysis performed on UKBB individual-level genotype data among European-ancestry participants with highlighted novel independent signal and known index SNP, respectively, as an LD reference variant (colored purple). The **second plot** is a regional association plot based on conditional eGFR association analysis conditioned on known index SNP performed on UKBB individual-level genotype data among European-ancestry participants with the novel independent signal as LD reference variant (colored purple). The **third plot** is a regional association plot based on conditional eGFR association analysis conditioned on a novel independent signal performed on UKBB individual-level genotype data among European-ancestry participants with known index SNP as LD reference variant (colored purple). The details of the conditional eGFR association analyses were explained for each plot separately.

Figures 58-59: Colocalization of eGFR-associated known index SNPs with gene expression (*cis* eQTLs) across all tissues. **Figure 58** and **Figure 59** depict colocalization results based on unconditional and conditional eGFR association analyses, respectively. Genes with at least one posterior probability of colocalization ($PP \geq 80\%$) across tissues (x axis) are shown with the respective underlying variants and chromosome numbers (y axis). Colocalizations are illustrated as dots, where dot size corresponds to the PP and are colored according to the predicted change in gene expression relative to the lower eGFR. Color coding on y axis reflects locus.

Figures 60-76: Represent colocalization results for known index SNP and novel independent signal at each locus across all tissues. **Plot A** and **Plot B** show posterior probability of colocalization (PP of one common variant) based on eGFR association analysis (y axis) and conditional eGFR association analysis (x axis) for known index SNP and novel independent signal, respectively. The gray dash line represents $PP = 80\%$, with high evidence for colocalization ($PP > 80\%$) shown in color and low evidence ($PP < 80\%$) shown in gray. The blue dashed line corresponds to the diagonal line. The details of the conditional eGFR association analyses were explained for each plot separately.

Figure 1: Regional association plot for index SNP rs1397764 (3:141750810_A/G) and secondary signal rs147877018 (3:141813349_G/A) using eGFR association analysis.

Figure 2: Regional association plot for secondary signal rs147877018 (3:141813349_G/A) using conditional eGFR association analysis (conditioned on index SNP).

Figure 3: Regional association plot for index SNP rs1397764 (3:141750810_A/G) using conditional eGFR association analysis (conditioned on secondary signal).
